THE EXPERIMENTAL METHOD: ITS INFLUENCE ON THE TEACHING OF MEDICINE [*]

RICHARD M. PEARCE, M.D.
PHILADELPHIA

The phase of experimental medicine which I am about to discuss is "Experimental Medicine: its methods, what it has accomplished; the problems before it; and what it may hope to do in the future." I intend to point out, at the risk of being misunderstood, the importance of the experimental method in the everyday work of the student and the teacher of medicine; and how, if conscientiously applied, it may thus exert a powerful influence in the development of the science of clinical medicine.

It is my profound conviction that the greatest fault in our medical teaching is the failure of the majority of teachers to practice, when in actual contact with the students, those scientific methods which they recommend in theory, and which some of them vigorously apply in their own investigations. I would not have entered into this discussion if it were not that our product, our graduate in medicine, has been found wanting by the German finishing school. Prof. Graham Lusk, than whom there is no more fearless champion of scientific idealism, stated in a recent address that a friend was told by a prominent professor of medicine in a German university that the greater number of young Americans who came there to study were "no good." Twenty-five years ago such a statement would not have been surprising, but now, with our much-vaunted laboratory methods and our improved clinical teaching, the statement is, to say the least, discomfiting. The "greater number" of American students going abroad may be from the poorer schools, and if so, which hardly seems probable, the criticism is unjust to our schools of the better type. If, however, it represents the true condition, from the German point of view, then, as Lusk puts it, "our educational system is at fault. It cannot be that American intellect is inferior. The trouble lies in our system."

It is these statements which have crystallized my own misgivings as to the shortcomings of our methods of instruction. These shortcomings may occur in the laboratory work of the first two years or in the clinical work of the third and fourth years, but the teachers in the laboratory years are responsible for the point of view with which the student approaches the material of the clinician, and they should consider it not only a duty but a privilege and an opportunity of the greatest moment to train the student in method and in accuracy of observation.

Is this opportunity grasped by the man who sees his class only as it is seated in the amphitheater, who lectures four or five times a week and never or hardly ever goes into the laboratory where his students are at work? And what shall we say about the man who reads his lectures, the students acting the part of efficient stenographers, fearful of missing a word, because, without emphasis of important points, they must get every word for the necessary and inevitable cram? And then, most ludicrous of all, the man who lectures from his own text-book, his auditors not taking notes but underlining the text of the same book?

Complete, voluminous, detailed lectures may have been necessary in the days of poorly prepared students, but with our present requirements in physics, chemistry, biology and the languages they are unnecessary. The department head who inaugurates his week's work with a general summary of the character of the laboratory exercises of that period, emphasizes the important phases of the subject and suggests the matter to be read, can leave the details which take the time of the second, third, fourth and fifth lectures to the student himself and to amplification in the laboratory. Or, if this does not suffice in his mind to present the subject-matter properly, a second hour with the lantern is worth half a dozen formal lectures. At the end of the week, after the laboratory work is completed, a third hour, for a conference recitation, which he conducts personally, should clear up all doubtful points. In this recitation the men should not be marked; it should be an informal affair, with the sole object of determining the efficiency of the week's instruction and of the progress in the power of observation and deduction.

Complete presentation of a subject in a lecture, even though the facts be retained, stifles curiosity and inquiry, turns the interest of the student backward instead of forward, and retards the development of that scientific method of thought so satisfying as a part of one's mental equipment. Complete and voluminous lectures which discourage collateral reading and minimize individual laboratory work, force the student to consider the final examination to be the ultimate object of the course. In some schools the student is encouraged in this point of view by the establishment, often with the consent and approval of the head of the department, of extramural quizzes, which, given by assistants of the department, increase the income of the latter at the expense of the student's mental development.

Another fault of the lecture system is the not infrequent arrangement which allows the head of the department to consider lecturing his only duty and permits him to turn over the laboratory work to assistants. If the laboratory instruction is to be not merely a matter of perfunctory routine, but is to be used for training in the experimental method with the object of developing power in method and in observation, it becomes one of the most difficult forms of teaching, and no matter how adequately trained the assistants may be, the daily presence of the head of the department, if he have the proper point of view, is essential to the success of the laboratory instruction.

---

[*] An address delivered at the Harvard Medical School, May 18, 1911, under the auspices of the Alpha Omega Alpha Honorary Medical Fraternity.

[*] Owing to the lack of space this paper has been reduced nearly half. The unabridged article is printed in pamphlet form and will be sent by the author, or by THE JOURNAL, on receipt of a stamped directed envelope.

Let us now turn to the instruction in the laboratory itself, where we should certainly expect to find experimental methods conscientiously practiced. We have every reason to be proud of the equipment and facilities of most of the laboratories in our better medical schools.

The guiding principle of laboratory instruction should be the practice of the "do it yourself" idea. Lectures, amphitheater demonstrations and recitations should, if time cannot otherwise be obtained, give way to actual individual work in the laboratory. Furthermore, the department head, without sacrificing the presentation of his subject as a training in method, should prominently place before the student its relation to other courses in the medical curriculum, and especially to the clinical work which is to follow.

Nearly all our laboratory courses offer opportunity for criticism from these two points of view. Anatomy, aside from the fault of overlecturing, is perhaps least at fault, for abundant material for dissection makes this course, if the material is properly utilized, an ideal one for the practice of the "do it yourself" method. The related subjects, histology and embryology, may, however, be criticized in that they are seldom taught in relation to one another or to gross anatomy, and practically never with a regard to the work in physiology and pathology which follows. Of the few exceptions, Huber's course at Michigan best illustrates how these subjects should be presented. Embryology forms the basis of the work in histology; the student studies cell division and the development of the germ layers, and as the tissues and organs are differentiated the histology of each is studied in adult tissues. Thus the structure of each adult tissue and organ is brought into relation on the one hand with its origin and its order of development, and on the other, by judicious correlative teaching, with important basic principles of pathology; as, for example, the general laws concerning the origin of tumors, or the similarity of the repair or regeneration of an adult tissue to the embryonic development of the same tissue, or the developmental explanation of the anatomy of hernia. These and other important fundamental principles can be taught better by the embryologist than by the pathologist.

Another neglected field is that on the border-line between histology and gross anatomy, which for the want of a better name may be called "semi-gross" anatomy. The well-trained student can from memory give a fairly accurate description of the relations and gross external appearance of an organ and also of its histologic structure, but he is at sea when asked to point out on the freshly cut surface of an organ its normal markings. The appearance of the Malpighian bodies of the spleen, of the glomeruli of the kidney, the differentiation of arteries or veins from the bronchi in the lung or from the bile-ducts in the liver are matters of which he knows nothing. His theoretical knowledge fails when put to the practical test.

It is, however, of the work in physiology, pathology, *bacteriology and pharmacology* that I wish especially to speak. The first and second of these sciences are concerned essentially with normal and abnormal functions the third with one phase of the etiology of altered function and the fourth with the treatment of abnormal function. They therefore lend themselves to teaching from the dynamic rather than from the static or descriptive point of view, and are peculiarly adapted to the procedures of the experimental method. These are subjects which offer the possibility of bringing the student closer to an understanding of the manifestations of disease, and the factors which cause and influence these manifestations, than any other group of subjects in the medical curriculum. Physiology and pathology should be so taught as to force the student and physician to think physiologically and not morphologically, as is usually the case. The close adherence of both of these sciences to the descriptive method may be explained historically in the case of physiology by the development of physiology by anatomists, physicists and chemists rather than by biologists in the broad sense. The influence of the descriptive anatomist is seen in the early association of histology with physiology; of the physicist in the early electrophysiology, and of the chemist in the early analytical trend of physiologic chemistry. Likewise, pathology, adopting the methods of anatomy, became a purely descriptive science, seeking the seat of disease and concerned with the appearance of diseased tissues.

In investigation, the descriptive point of view is now subordinate, but in teaching it still persists. The student in physiology, in many schools with well-equipped laboratories, never works with an animal higher than the frog. Such a course in electro-physiology, essentially a course in physics, with a few exercises devoted to the use of mechanical models and perhaps a few amphitheater demonstrations, is considered sufficient training for the work which soon follows, in the instruction, for example, in physical diagnosis. The student enters on the latter work, which many consider the most difficult part of their course, with no first-hand knowledge of the important phenomena of circulation and respiration, which might readily have been presented by the use of mammals. One of the most useful instruments of the physician, the stethoscope, of great value also in the teaching of physiology, is seldom utilized. In many courses the *physiology of respiration and circulation* is completed without the student having heard the respiratory murmur or the heart sounds. The physiology of the kidney, the pancreas and the ductless glands is taught by lecture only, or by an occasional amphitheater demonstration.

Bacteriology, one of the most modern of the medical sciences, suffers likewise from the descriptive method. It is, in the majority of schools, a course in the *descriptive* botany of the fungi. It is true that the student actually handles the bacteria, studies their morphology and observes their behavior in artificial media, but their behavior in the animal body is left to lectures. The all-important lessons of bacteriology—the problems of infection and immunity—the student has no opportunity to study at first hand. What a live subject bacteriology may be for the student is seen in those few courses in which he reproduces in animals the lesions caused by the micro-organisms which he studies, and carries out those experiments which illustrate the fundamental principles of immunity. He can have no better training in the experimental method than that which comes from following half a dozen different bacteria from pure culture through the lesions which each produces in an animal and back again to pure culture. Likewise, the experimental study of active and passive *immunity, even if the* latter be only the simple testing of the protective power of diphtheria antitoxin, is invaluable. If to these are added the practical study of hemolysins, agglutinins, precipitins and of the phenomena of hypersusceptibility, bacteriology as applied to medicine is actually taught. From the practical point of view, the training offered by animal inoculations is of the greatest importance for the proper appreciation of the principles of asepsis in surgery; while the work in immunity aids the student to grasp intelligently the pathology and therapy of the transmissible diseases.

It is a matter of great doubt if in the better schools to which students come with a general training in biology it is necessary to give as much time to the purely morphologic study which consumes so much time in the average course in bacteriology. Certainly this phase of the subject, with the abundance of excellent text-books which we possess, does not demand the number of lectures usually devoted to it. The present methods do not give the student an adequate general conception of the rôle bacteria play in disease, and of specific effects they have no knowledge which they can readily apply to their work in pathology.

And what is to be said of pathology? I consider pathology, as it is usually taught, the most forlorn course in the medical curriculum. Lectures in great abundance, illustrated by museum specimens enclosed in fluid and glass and sections of diseased tissues sandwiched between glass is the story in nine out of ten cases. Even when fresh material is supplied in satisfactory amount, a gap still remains—that great gap representing altered physiology. I do not wish to decry any means by which a knowledge of pathology may be presented to the student, but an adequate collection of specimens representing the gross and microscopic appearance of diseased tissues should, I believe, be considered as only the essential minimum of equipment. Neither do I wish to minimize the importance of morphologic study, for it is the cornerstone of that modern pathology on which sound diagnosis and rational therapy rest; but the teachers of men who are to spend their lives in the study of the manifestations of altered physiology should not magnify the morphologic aspect of pathology at the expense of the dynamic. This phase of my subject in so far as it refers to investigation has been very ably discussed from the point of view of the chemist by Prof. A. E. Taylor; and the possibilities of physiologic methods in teaching pathology to small groups of students have been clearly demonstrated by Prof. W. G. MacCallum. So ably have they presented their claims that I can add but little that is original. My personal experience may, however, be of some value as an illustration of the evolution of a point of view. Trained as a morphologist of the most uncompromising type, I became interested, after several years, in the methods of an experimental pathologist and gradually awakened to the importance of the investigation of altered function. A desire for a greater knowledge of the methods of physiology and chemistry followed. At first this new knowledge was utilized only in investigation but a troubled conscience soon led to its use in the teaching of pathology. At first, experimental demonstrations before the entire class were introduced here and there in my courses, but in such a fragmentary way that they were of no more value to the student than the usual set demonstration of the chemist. This year, for the first time, I found myself with sufficient space, equipment, time and assistants to inaugurate a systematic course in experimental pathology and pathologic physiology in such a manner that each student would get something out of it. Without going into the details I may say that by giving two hours a week to the course and dividing the class in two sections, each student of a class of ninety men had fourteen exercises of an hour each, and by presenting in each hour five different demonstrations simultaneously, no one demonstration group numbered more than nine men. That is, about seventy experimental procedures, phenomena or lesions, were shown each man, for each of which he had twelve minutes and was only one of a group of nine.

These demonstrations included the presentation of necrosis and the degenerations, inflammation and repair, blood-destruction and jaundice, thrombosis, embolism and infarction, certain lesions of the heart, lung, stomach and intestines, liver, pancreas and kidney, the problems of infection and immunity, of shock and hemorrhage, and the physiology of the ductless glands. Physiologic methods of graphic registration were used whenever possible, changes in the urine and other secretions demonstrated, and the methods of clinical diagnosis emphasized. A few details of some of the exercises may illustrate the advantages of this course. The pathology of blood-destruction and jaundice, the circulatory changes in heart disease, and the pathology of the pancreas are subjects always difficult for the student to grasp; and, moreover almost impossible of demonstration by morphologic methods. The exercises on these subjects may therefore serve as examples. Blood-destruction and jaundice were illustrated by five demonstrations: (1) the production of hemoglobinemia and hemoglobinuria by the administration of crotalus venom, and (2), the injection of hemolytic immune serum. The associated changes in the spleen and other organs were demonstrated, as was also the laking of the blood in centrifuged serum. The naked eye appearance of the urine was contrasted with that of (3) hematuria due to cantharidin, as were also the albumin content and sediment of the two types of urine, and the use of the spectroscope was demonstrated. By test-tube experiments the phenomena of (4) hemolysis and hemagglutination were explained, and thus the theory graphically brought into relation with the changes in the animal body; (5) obstructive jaundice due to ligation of the common bile-duct was shown, the urine of this animal contrasted with that of the hemoglobinuric animals as to the presence of bile and albumin, and by comparing these animals the clinical signs of obstructive and hemolytic jaundice were clearly shown by examination of the skin and conjunctiva.

In the exercise on cardiovascular disturbances the changes in heart action, blood-pressure, pulse-rate and volume, and in respiration as a result of experimental (1) aortic insufficiency, (2) mitral stenosis, (3) hydropericardium, (4) injury to myocardium and (5) edema of the lungs, were graphically demonstrated by the use of a kymograph.

Acute diseases of the pancreas were illustrated by (1) experimental acute hemorrhagic and (2) gangrenous pancreatitis due to the injection of bile, with (3) the correlated fat necrosis. The relation of the pancreas to diabetes and the theory of internal secretion were demonstrated by contrasting the results of (4) extirpation of the pancreas with (5) ligation of the pancreatic ducts. The fermentation and Fehling's tests applied to the urine of all these animals offered a vivid picture of the relative influence of different types of injury of the pancreas.

These three exercises are examples of the opportunities offered by this method of teaching. The advantages of its application to the problems of nephritis, the disturbances of the ductless glands and the principles of infection and immunity are evident. No other part of my teaching experience has ever given me so much satisfaction with the attitude of the student, and in no other course have I felt so certain that I was giving him what he wanted and needed. Such a course is, after all, as near an approach to clinical methods as one can attempt in the laboratory. The physician studies the altered functions of his patient by direct observation and by all the methods which biology, physics and chemistry have brought to bear on diagnosis; he summarizes the results, correlates them, ponders over them and arrives at a conclusion which is based largely on the fundamental experience of pathologic anatomy. His work really represents the first, the oldest, and the most important application of pathologic physiology.

Another phase of the teaching of pathology which may be criticized is the presentation of pathologic anatomy. Diseased organs are studied from the point of view of changes in morphology, color and consistence, without attempt to associate physiologic disturbances. In many schools no systematic work in gross pathology is offered after the second year, and even in the second year it is usually a museum course with no systematic drill in fresh appearances. Some schools have improved the situation by obligatory autopsy work and clinicopathologic conferences in the third and fourth years. Also the museum material has had some life instilled into it by adopting the "case" system of presenting organs illustrating the associated lesions of any one disease with, at the same time, the clinical history and microscopic preparations. But all these improvements leave the work a demonstration course. The student can obtain an adequate knowledge of morbid anatomy only by following the example of the young pathologist; that is, by studying at first hand the naked-eye appearance of fresh organs, arriving at some conclusion, and immediately verifying it, or otherwise, by the use of the freezing microtome. This is the true experimental method—observation, hypothesis, experiment, deduction. It is perhaps, best combined with the work of the third and fourth year of medicine after the student has had a year of fundamental pathology, though if time allows it can also be used in the second year. During the past four months I have used it with my third-year class and have had the most gratifying results. Placed in a room with the fresh material before them, with scales, measures, the necessary dissecting instruments, a bacteriologic outfit, stains and reagents for microchemical reactions, an abundance of text-books on all branches of medicine, and a laboratory attendant at the freezing microtome, the men have worked out their own diagnoses at first hand. No demonstrations were given and no aid, except in guiding methods of procedure and by occasional pertinent questions. At the end, diagnoses were checked, and each student's general knowledge of the lesions he had studied was determined by a few leading questions as to etiology, associated conditions, complications, sequelæ, and important clinical symptoms. The eager attitude of the class toward this course has been sufficient evidence of its value.

We have not the wealth of fresh autopsy material offered by the pathologic institutes of Germany, but that which we have is too frequently used for perfunctory demonstration or for second-hand study as beautifully mounted and labeled museum preparations and not sufficiently utilized for first-hand observation and manipulation by the student. The use of fresh material and the freezing microtome go far to wean the student from his "reverence for authority" and his faith in the lecture and to force him to observe and think for himself.

Physiologic chemistry and experimental pharmacology, as given in our best schools, are, I believe, the most satisfactory of our laboratory courses. Presented, in most instances, in a vigorously scientific manner, with the student carrying on exact quantitative estimations and using graphic methods of registering results, and himself frequently the object of experiment, these courses fulfil all the rules of the experimental method and force on the student, as no other course does, the practical importance of this method. To one who was taught by the methods of the old "medical chemistry," it is most stimulating to see an entire class in modern physiologic chemistry study the influence of a protein, a fat or a green diet, of a nuclein diet on purin output, of a heavy protein diet on urea output, and of starvation on total nitrogen and acetone elimination. In these, as well as in other procedures, as individual calorimetry with the respiration apparatus, the student is the investigator as well as the experimental animal. Such experiments are now extensively carried out in a few courses, and when supplemented by the study of phloridzin glycosuria, pancreatic diabetes and other experimental conditions in animals, give a knowledge of the fundamental principles of metabolism and of practical physiologic chemistry which was not dreamed of by the student of ten years ago. Such courses lead one to believe that the rapidly approaching closer union of hospital and school will lead to the next step, the opportunity for small classes to study the metabolism of patients in the hospital ward.

The modern course in experimental pharmacology, unfortunately at present not given in all our better schools, is I believe, the most valuable part of the first two years of laboratory work. Coming as it usually does in the latter part of the second year, when the student is completing or has completed his physiology and pathology, it offers him the last opportunity, before he approaches the clinic, to review normal functions and to study the manner in which various agents may alter them. And in those courses which are not merely exercises in testing the action of drugs, but in which abnormal conditions are produced and measures for their treatment or care are applied, pathology as well as physiology is reviewed and the fundamental principles of therapeutics thoroughly impressed on the student's mind. Not only medicine, but surgery, benefits by such a course, for the study of the influence of anesthetics and of the production and treatment of shock, collapse and hemorrhage carries the student well into the realms of clinical surgery. I refer, naturally, not to demonstration courses, but to those in which the procedures are actually carried out by the class.

In presenting this criticism I am not unmindful of the recent great advance in the utilization of laboratory teaching, and I realize fully that suitable equipment for teaching must precede the elaboration of methods of teaching. This equipment we now have in all good schools and I feel very strongly that the time has arrived for the heads of the laboratory departments to justify its great expense by so conducting their courses as to satisfy, on the one hand, the students receiving the instruction, and on the other, the trustees or others providing the equipment. But, above all, they must themselves be satisfied that their courses, collectively, leave no gaps which might, with a little thought and a little cooperation, be filled. Some of these gaps, as, for example, those I have mentioned in connection with bacteriology and pathology, could be filled by new departments of immunology and pathologic physiology, but the already overburdened medical curriculum cannot yield more time. Correlation between various departments and a rearrangement of old courses on a modern basis, with the object of training for power rather than knowledge, must be one of the remedies. The present evil is the result of a lack of general supervision. One remedy, therefore, is open criticism backed with authority, and that authority should reside in a committee of the governing body of the university. This is the most direct way to bring about a proper correlation but not, perhaps, the best way.

Another method is by voluntary cooperation on the part of the heads of the laboratory departments. Our medical sciences are not, for the most part, so widely separated that members of one department are totally ignorant of methods of another. Their interrelation is best illustrated by the development of embryology in the departments of anatomy, physiology and zoology simultaneously; by the influence of pathology on physiology and on the development of certain phases of normal histology; by the position which bacteriology and protozöology occupy in the departments of pathology and hygiene; by the development of a new science, modern pharmacology, based on the application of the methods of chemistry and physiology to empirical therapeutics; and by immunology, as its followers now term it, which demands the methods of practically all the medical sciences.

Despite this history of development and mutual relation there is a tendency, not only in teaching, but in investigation, to separate sharply each of these into an independent science of medicine to the great detriment of that which should be the scientific aim of all, the development of the science of clinical medicine. Even though this last science is to reach its perfection only through the efforts of men actually engaged in clinical research, as is the opinion of Dr. S. J. Meltzer, such men must receive every advantage of training in the fundamental medical sciences, and not only this, but from the teachers of such branches they must receive so much of the scientific spirit that they will carry some of it with them into their clinical work. I do not mean by this that clinical surgery and medicine have not men of scientific methods and investigators of prominence; I mean rather that they would have more if the teachers of the first two years so correlated their work as to force on the student the practical use of their methods in the investigation of clinical problems, or, what is simpler still, demonstrated the relation which the methods of one course bear to those of another course in the explanation of the phenomena of abnormal function. This latter is particularly the opportunity of the courses in physiology, pathology and pharmacology. The benefit of such cooperation cannot be denied and illustrates a second of the possible remedies for the present isolation of our laboratory courses.

Another important phase of this subject is that of the relation of investigation to teaching. If one examines courses in the same subject in a number of schools, it is found that those which are best presented from the point of view of the experimental method are under the control of men actively engaged in research work. Such men are alive to the advantages of new methods in their own subject and of new ways of applying old methods. On the other hand, one finds that the perfunctory routine laboratory courses, with a profusion of lectures, are by the men who never or only occasionally contribute to the literature of their science.

I have often thought that our departments of biologic chemistry and experimental pharmacology forcibly illustrate the importance of the investigator as a teacher. With few exceptions, they are manned by active investigators and from the point of view of medical pedagogy are most satisfactory. They represent, as now organized, the most recently developed of the medical sciences, and have emerged directly from the fields of most active investigation in physiology and chemistry. They have no vast theoretical literature back of them, no traditions as to methods of teaching, but they have established their own methods on the basis of observation and experiment. "Medical chemistry" and "therapeutics" were once taught by "good teachers," but the investigator in physiology and chemistry has transformed them into sciences of university rank to which the former narrow terminology no longer applies.

These three factors—authoritative control to arrange correlation, cooperation by department heads, and the appointment of teachers who are also investigators—are fundamental in the application of the methods of experimental medicine to proper teaching. Two other factors, however, are concerned. These are closely related. One is the question of electives and the other the question of actual research by the student. The first, necessary for any proper attempt at correlation, is obligatory if the student is to work independently, even in a small way, as an investigator. As the advisability of giving the student the latter opportunity is still a disputed point, however, it may be discussed first. As every teacher knows, each class contains a considerable number of men who desire to pursue, to a greater extent than the conventional course allows, work on certain subjects or by special methods, or less frequently, perhaps, they desire, and are usually well qualified to undertake, minor investigative work. To the former, as well as to the latter, any effort spent in work beyond that given the entire class becomes, necessarily for them, the acquirement of the methods of research, and as this means a knowledge of the exact, painstaking methods by which the realms of the unknown are explored, it is an exercise which prepares the student for the daily routine research work of the physician who truly practices his profession. As a training for future work, its value is definitely known and the increased zest and enthusiasm exhibited towards their medical work by men who have had this opportunity are always evident. Pedagogically, therefore, it would seem advisable that every student should have the opportunity for minor research, in order that he may become acquainted at first hand with the careful methods of experimental medicine. The bearing of the tangible results of his work on the subject investigated is a matter of little or no importance; the vital thing is the increased power which he himself acquires. If the student is to have such opportunity the elective system is necessary.

So much for the use of the experimental method in the two laboratory years. This method, if it has any special significance, should bear fruit in the third and fourth years, the periods devoted to clinical teaching. Are our clinical departments so organized that they are prepared to aid the student in his development along scientific lines? A few are, but for the most part the clinician returns the student to the methods of the lecture-room and the demonstration and gives him little opportunity to develop his powers of personal observation. The discussion of this phase of teaching may be limited to the department of medicine, as contrasted with surgery and the specialties, though what is said of medicine applies equally to other clinical branches. The department of medicine should be the great glory of the medical school, and the method of instruction in all preceding courses should be considered as contributing to the proper study and appreciation of the material and problems of clinical medicine. Pedagogically considered, the methods of study in the earlier years should give the student the proper point of view for approaching any diseased condition, and practically, they should train him as far as may be possible in the actual methods of precision used in the clinic. The methods of the diagnostician are those used in procuring all scientific data; that is, accurate observation and experiment with logical deduction. His observations are of two kinds, direct, by the exercise of his unaided senses, and indirect, by the use of instruments of precision and various laboratory procedures. These demand methods which from the pedagogic point of view are in no way different from the methods used by the student in his laboratory years.

The data obtained, either directly or indirectly, when correlated according to the rules of the experimental method, lead to a conclusion (diagnosis) as scientific as the conclusions of the investigator in the laboratory of physiology or pharmacology. If it should eventuate that the conclusion is erroneous, it is not the fault of the experimental method but of inadequate methods, insufficient data or improper deduction. Clinicians of long practice will not always admit that the data on which they base a diagnosis are always obtained by the careful, painstaking methods of scientific observation. They imply that experience gives an added sense, forgetting that it is the continuous training in accurate observation and deduction which gives them the power to make and correlate their observations rapidly and to reach their conclusion by a "short cut" not possible to the beginner. That knowledge of medicine which is of lasting value the student can get only from direct study of the patient. By direct study, I do not mean the study of the patient by a class, no matter how small, but the study of one patient by one student, under a supervision which tells him, to some extent, what to do and how to do it, but not what he is to find; in other words, a continuance of instruction in methods, leaving the matter of deduction in large part to the student himself.

The conduct of such a course brings up several of the problems now attracting the attention of all who are interested in medical education. It cannot, it is evident, be successfully given in a hospital not an integral part of the university. This is the experience of all schools which have attempted it in hospitals with which they are affiliated but in which they have no authority. Questions of authority over patients, of equipment for teaching, of laboratory space for clinical study, all indicate that the first essential is the possession or control by the school of its own hospital. This allows an easy solution of all problems: Continuous service and freedom in the appointment of clinical teachers come as a matter of course. Teaching and investigation can be carried on without interruption. The student becomes a part of the hospital routine and is not an onlooker with limited privileges. The laboratory departments of the first and second years unite to aid the work of the clinicians in the hospital. Clinical teachers may be promoted, if deserving, or may be called from any part of the country, or from abroad; the choice no longer depends on local hospital appointments or on the selfish interests and friendships of local consultants, but on fitness, eminence and skill.

Whatever has been said about the instruction in internal medicine applies with equal force to surgery, pediatrics and obstetrics. These four subjects constitute the backbone of medical knowledge, and the last three deserve a word of comment. Pediatrics, frequently served by special hospitals, is amenable to the same individual teaching as internal medicine, and because of its peculiar importance should have a more prominent place in the medical curriculum than is usually assigned it. Obstetrics presents special difficulties because of the infrequence of maternity wards and also on account of the wide scattering of the out-patient service, but these difficulties are not insurmountable.

Surgery, from the point of view of diagnosis and the care and treatment of the minor common lesions and injuries, may be taught by the same methods as those outlined for internal medicine, and, most important of all, the frequent lectures and large operative clinics from which the students gain little or nothing, should be replaced by courses in experimental and veterinary surgery, offering an opportunity for detailed training in the administration of anesthetics, in asepsis and antisepsis, in the preparation before and the care after operation, and above all for the study of repair of wounds and their treatment.

Much of surgery and of the various specialties should be given as elective courses, in the manner adopted by this school, or as postgraduate work. No physician needs to know, or can know, all the specialties in detail, and only a relatively small number become operating surgeons. Those that do specialize, do so only after a thorough postgraduate training. The great bulk of men who practice medicine should have as thorough a training in internal medicine and closely allied branches, such as pediatrics and neurology, as it is possible to give. With this, in the obligatory course should go a general knowledge of the principles of surgical diagnosis and a certain minimum knowledge of the specialties.

One or two other matters of importance in the teaching of clinical medicine may be briefly mentioned here. One of these is the advisability of offering small groups of students the opportunity of studying, as an elective, the diseases of one organ, or of related organs, from every point of view. I have been much interested in such a course given last year by Dr. W. T. Longcope at the University of Pennsylvania and known as a course in "medical correlation." During one year a group of six students studied the diseases of the heart from the clinical, the pathologic, the experimental and the therapeutic point of view. All the methods of clinical observation were brought to bear on the cases in the wards of the hospital; gross and microscopic preparations illustrating the pathology were examined; the normal physiology of the heart was studied in animals by the methods of physical diagnosis and of graphic registration, and finally these were used also in the observation of lesions produced experimentally. The relation of various diseases of the heart to diseases of the lungs, liver, kidney and other organs and tissues was thoroughly covered and the effect of treatment on patients in the wards and experimentally produced lesions in animals observed.

Another matter concerns departments in the medical school known as research departments and variously described as departments of experimental pathology, experimental medicine, or research medicine. The title matters little, but the plan of the department should be broad enough to care for the problems of clinical medicine, and for this reason the word "medicine" should appear in the title rather than the word "pathology." Such a department should keep in close touch with the department of clinical medicine, and should supplement the facilities of the various hospital laboratories, but, nevertheless, should also work in cooperation with the fundamental laboratory sciences in order to insure a realization of the greatest good to the school. The head of the department should be a man familiar with the problems of clinical medicine trained preferably as a pathologist, and with sufficient knowledge of the possibilities of physiology and chemistry to apply the methods of these subjects to clinical problems. I say preferably a pathologist because the pathologist is more apt to combine clinical training with a knowledge of pathology, bacteriology and the principles of immunity than is the physiologist, chemist or pharmacologist, though any one of the latter might well head such a department.

The work of this department should be the investigation of clinical problems, and not of academic problems of pathology, chemistry, physiology, etc. The latter can still be carried on in the departmental laboratories which have always followed academic lines, and, in truth, are forcing, through their neglect of clinical problems, the establishment of the type of department described. General practitioners, clinical assistants in the school, and even those at the head of clinical departments are constantly meeting problems which demand solution but find no adequate opportunity to investigate them in departments as now constituted.

Another function of this department should be undergraduate instruction to fourth-year men taking research work in clinical medicine as an elective, and also postgraduate instruction for those desiring training in the methods of experimental medicine as the basis for a career as teacher or investigator.

The practice of medicine has developed out of empiricism by the application of the methods of its tributary sciences and whatever is definitely known and understood in medicine can be traced to the application of the experimental method.

In recommending to you that, as practitioners, you keep always the point of view of the investigator, I realize fully that as you go out among so-called "practical" doctors you will find many who sneer at what they term the "scientific" doctor. This view, of which we hear less and less each year, is a survival of the opinion commonly held prior to the development of the sciences of bacteriology and physiologic chemistry, which sciences, by their practical applications to every-day medicine, have perhaps done more to dispel it than is usually realized.

I have read recently an address by President MacLaurin in which he discusses some of the factors which in the course of fifty years have placed the Massachusetts Institute of Technology in its present commanding position. Two of these factors are worthy of the earnest consideration of the trustees and teachers of our medical schools. The first President MacLaurin presents as follows: "There has never been any uncertainty or indefiniteness as to what the institute is aiming at in its scheme of education;" the second, embodies the idea that the success of the educational policy of the institute has been due to the fact that the emphasis has been laid on the *"method"* and *spirit* of science rather than on *subject,* and that the *"learning by doing"* or *"do it yourself"* idea has been systematically applied. We need, in medicine, a greater appreciation of both these factors by our trustees as well as by our teachers; of educational policy by the former, of educational method by the latter.

THE RELATION OF THE INTOXICATING DOSE OF HORSE-SERUM TO THE PROTECTIVE DOSE OF ATROPIN IN ANAPHYLAXIS IN THE GUINEA-PIG *

HOWARD T. KARSNER, M.D.
Assistant Professor of Pathology, Harvard Medical School
BOSTON
AND
JOHN B. NUTT, M.D.
PHILADELPHIA

Within the past two years Auer and Lewis[1] and Auer[2] have shown that atropin sulphate has a distinct protective action against the asphyxia of immediate or acute anaphylaxis in the guinea-pig, and their observations have been repeatedly confirmed.[3] Inasmuch as most of these studies have had for their purpose the determination of the physiology of anaphylaxis, no attempt has been made to determine the quantitative relation, if such exists, between the intoxicating dose of the serum and the dose of atropin sufficient to protect the animal from death. The study presented in this paper had for its object the determination of this point.

The problem was attacked from two sides. First, with a minimum fatal dose of horse-serum as a standard, the minimum protective dose of atropin was determined; the toxic dose of serum was then increased and the minimum protective dose of atropin again determined, this procedure being repeated until the dose of atropin became so large as to be markedly toxic for the animal. Second, a maximum dose of atropin, just short of the lethal dose for the animal, was administered and a determination made of the largest amount of horse-serum against which the dose of atropin protected the animal; the dose of atropin was then diminished and the maximum nonfatal dose of serum again determined. This procedure was continued until a point was reached where further reduction in the size of the dose of serum would in itself have failed constantly to produce death. Throughout the study a constant sensitizing dose of 0.05 c.c. of horse-serum was used. After a lapse of sufficient time for the animals to become actively hypersusceptible the dose of atropin was given into the exposed right jugular vein and the intoxicating dose of horse-serum three to ten minutes later into the same or opposite vein. All animals were closely observed in their cages and autopsies performed on those that died. It was found in the latter that the lungs were somewhat more congested than is the rule with typical anaphylaxis;[4] the myocardium often showed punctate hemorrhages, and the abdominal viscera were much congested but free from macroscopic hemorrhage.

TABLE 1.—RELATION OF MINIMUM FATAL DOSE OF SERUM TO MINIMUM PROTECTION DOSE OF ATROPIN

Number of Animal	Dose Atropin Sulphate in Gm.	Time in Minutes Between Injections	Intoxicating Dose, Horse-Serum, in C.c.	Symptoms	Result
555	0.001	10	0.2	Increased respiratory rate with dyspnea.	Recovery.
556	0.001	10	0.4	Severe..............................	Death (5 minutes).
561	0.002	5	0.4	Marked respiratory difficulty............	Recovery.
563	0.001	6	0.6	Severe..............................	Death (5 minutes).
564	0.002	7	0.6	Marked respiratory difficulty, convulsions	Recovery.
565	0.003	6	0.8	Severe..............................	Death (5 minutes).
569	0.007	6	0.8	Moderate respiratory difficulty..........	Recovery.
570	0.008	6	1.0	Severe..............................	Death (1 minute).
571	0.010	6	1.0	Severe..............................	Death (8 minutes).
573	0.015	6	1.0	Severe..............................	Death (5 minutes).
577	0.020	3	1.0	Severe..............................	Death (30 minutes).
579	0.025	3	1.0	Moderate respiratory difficulty..........	Recovery.
580	0.030	3	1.5	Severe..............................	Death (5 minutes).
585	0.040	5	1.5	Severe..............................	Death (5 minutes).
...	0.040	..	...	Moderate increase of respiratory rate....	Rapid recovery.
...	0.050	..	...	Rapid cessation of respiration..........	Death (5 minutes).

TABLE 2.—RELATION OF MAXIMUM NON-FATAL DOSE OF ATROPIN AND MAXIMUM DOSE OF SERUM AGAINST WHICH ATROPIN IS PROTECTIVE

Dose Atropin Sulphate in Gm.	Time in Minutes Between Injections	Intoxicating Dose of Horse-Serum in C.c.	Symptoms	Result
0.015	5	1.5	Severe....................................	Death (5 minutes).
0.015	5	1.0	Marked respiratory difficulty; convulsions; coma....	Recovery. (Death, 18 hours).
0.012	5	1.0	Severe....................................	Death (5 minutes).
0.012	5	0.8	Severe....................................	Death (5 minutes).
0.012	5	0.7	Marked respiratory difficulty, but without complete cutting off of air supply..........................	Death (6 minutes).*
0.012	5	0.6	Moderate respiratory difficulty; slight general convulsions..............................	Recovery.
0.010	5	0.6	Severe....................................	Death (17 minutes).
0.010	5	0.5	Severe....................................	Death (8 minutes).
0.010	5	0.4	Severe....................................	Death (5 minutes).
0.010	8	0.3	Marked respiratory difficulty; convulsions..........	Recovery. (Death, 18 hours).
0.008	5	0.3	Marked respiratory difficulty; frothing at nose; convulsions..............................	Death (18 minutes).
0.008	5	0.2	Same symptoms as preceding..................	Recovery.
0.006	5	0 2	Slight respiratory difficulty..................	Recovery.
0.004	5	0.2	Marked respiratory difficulty; convulsions..........	Recovery.
.....	.	0.2	Severe....................................	Death (3 minutes).
0.018	.	...	General convulsions; respiratory failure............	Death (5 minutes).
0.015	.	...	General twitching; increased respiratory rate.......	Recovery.

* Apparently result of exhaustion rather than anaphylaxis.

The first phase of the study occupied about a month. For this reason the second injection of serum with its corresponding dose of atropin was given from twenty-five to fifty-five days after sensitization, the larger doses being given in the later periods. In the second series, however, the work progressed more rapidly, the time of sensitization being from seventeen to eighteen days; furthermore, the order of experiment was reversed in the second series, the larger doses being administered first. Any objection that might be raised on account of the varying time of sensitization in the first series is certainly overcome by the method of the second.

Table 1 presents the essential results of the first series of experiments. It is seen that the minimum fatal dose of horse-serum (0.2 c.c.) was insufficient to produce death when preceded by the administration of 0.001 gm. of atropin. In order to protect against 0.4 c.c. and 0.6 c.c. of horse-serum, it was necessary to increase the dose of atropin to 0.002 gm. To protect against 0.8 c.c. serum, 0.007 gm. atropin was necessary and against 1 c.c. serum, 0.25 gm. was needed. No dose sufficiently large to protect against 1.5 c.c. serum was possible, for before such a point was reached the animals succumbed to the dose of atropin. The presence of distinct symptoms of anaphylaxis in all those animals which were saved, is sufficient evidence of the fact that they were highly sensitive. It is clear then that there is a quantitative relation between the protective dose of atropin and the intoxicating dose of horse-serum.

---

[4] Karsner, H. T.: Die Lungen in Anaphylaxie und in Anaphylaxie gleichenden Zuständen, Ztschr. f. Immunitätsforsch., in press.

The second series is presented briefly in Table 2. Whereas the atropin used in the first series was from Smith, Kline, French & Co., that used in the second series was from Merck & Co. This fact probably accounts for the variance in absolute dosage of atropin seen in the two tables, for the animals of the two series were from the same general stock. Eighteen milligrams of atropin killed a guinea-pig within five minutes. It is seen that 0.015 gm. protects against 1 c.c. serum, 0.012 gm. against 0.3 c.c. serum, and 0.004 gm. against 0.2 c.c. serum. The minimum protective dose of atropin was not determined. The conclusion that there is a general relationship between the doses of atropin and serum is obvious. From the first series, it appeared that the curve of the dose of atropin rises much more rapidly than that of the dose of horse-serum, but this is not borne out by the results of the second series. That any such exact relationship could be demonstrated, was doubtful from the first because of slight variance in the individual susceptibility to the horse-serum. The same slight individual difference of response is seen in connection with the administration of atropin.

A STUDY OF FEVER IN TUBERCULOSIS WITH REFERENCE TO ITS CAUSATION AND TREATMENT *

FRANCIS M. POTTENGER, A.M., M.D., LL.D.
MONROVIA, CAL.

The fever which accompanies tuberculosis is a symptom poorly understood and unsatisfactorily treated. In recent years the opinion of the profession as to the chief factors in its causation has undergone several changes; and yet the most generally accepted theory at the present time is still unsatisfactory and leaves much to be explained. Since there can be no exactness in its therapy until we have formed some definite idea of its cause or causes, the importance of more study along this line is self-evident.

It must be obvious to anyone who has an opportunity to study patients suffering from advanced tuberculosis and who uses his powers of observation, that the cause of the chronic fever in tuberculosis and the factors which produce the irregularities in its course are numerous and complex. There has been an endeavor to make this subject entirely too simple and the result has been increased confusion.

The finding of bacteria of various kinds in the sputum of tuberculous patients, especially the pus-producers, has given grounds for the belief that tuberculosis, when it reaches the open stage, is a different process from that of early tuberculosis; and that the principal factors in the production of the symptoms in the later stages are the associated bacteria.

Koch[1] made the declaration that a daily temperature curve above 100.4 in a case of pulmonary tuberculosis is due to septic microorganisms and consequently unsuited to treatment with TR. This mixed infection theory was accepted by the profession generally. It called forth many such statements as these: "The tuberculous process is a dry process. If the tubercle breaks down it is because of mixed infection." "Cure the mixed infection and the tuberculosis will cure itself." "Any temperature above 100.4 is due to mixed infection." Such statements as these were believed in spite of the fact that the débris formed in cold abscesses is moist and yet free from pus microorganisms; and in spite of the fact that patients with acute miliary tuberculosis have high temperature curves before the tubercles have reached the age of softening. See Chart 7.

In order to understand the cause of these fevers, we must take a broader view and look at the question from many standpoints. I believe that the primary causes are at least three in number: the tubercle bacillus and its toxins; associated bacteria and their toxins; and enzymes and the products resulting from their action upon the body cells. This last cause is generally disregarded in discussions on this subject; and, yet, I believe it is a factor of great importance in all cases of advanced tuberculosis of the ulcerative type. I cannot help thinking that one of the greatest dangers to the tuberculous patient arises from the absorption of the products resulting from enzyme action.

Our knowledge of the action of enzymes is as yet comparatively meagre. The writings of Hahn,[2] Ascoli and Bezzola,[3] F. Müller,[4] K. Meyer[5] and Opie[6] are very suggestive and show the value of careful study along this line.

Two factors, the tubercle bacillus and the products of autolysis, are present in all cases of advanced tuberculosis. These factors are present in varying degrees which depend somewhat on the activity of the process. I do not believe that associated bacteria are an important etiological factor in the production of all fevers which rise beyond moderate elevations in advanced tuberculosis, although they are unquestionably so in some.

We are wont to look on tuberculosis of the fibroid form as being due to a type of bacillus of low virulence, believing that the greater the amount of toxins or the more virulent the bacilli, the greater the tendency to tissue destruction. This is a favorable form from the standpoint of cure. I doubt not that the comparatively small amount of autolysis present is also a very important factor in rendering this a favorable form of the disease.

The ulcerative processes, on the other hand, are more serious. We assume that the tubercle toxins are a greater factor in them than they are in the fibroid form. We also must recognize that these forms present a greater amount of autolysis. Where the tubercle bacilli are supplemented by associated bacteria, we have the severest form of the disease; for here we have both the effects of the various bacteria and their toxins and an increased autolysis.

We have attempted with a degree of success to classify these fevers and associate certain types of temperature with certain pathologic conditions. The continuously subnormal temperature we associate with both chronic fibroid tuberculosis and chronic tuberculosis of the ulcerative type during the stage of quiescence. (See Charts 1 and 2.) Doubtless in patients suffering from these types there is a minimum amount of tubercle toxins and products of autolysis entering the blood-stream; consequently there is little or no rise in temperature. Now, if the disease becomes active, however, and the tissues begin to soften, the entire range of temperature assumes a higher level as shown in Chart 3. The morn-

[6] Opie: Report of Sixth Int. Congress on Tuberculosis, Washington, 1908, p. 255; Jour. Exper. Med., 1911, xiii, No. 1, p. 162

ing temperature rises as well as that of the afternoon. I do not doubt that the tubercle toxins are a factor in producing this increase of temperature, but I am inclined to believe that the action of enzymes may be even a more important factor; for as Opie[6] says: "Injury to tissue is due primarily to the action of the tubercle bacillus, but the occurrence of caseation is perhaps distinctly referable to autolysis." The same conditions are present in what is termed caseous tuberculosis, as shown in Chart 4. Here we must consider that practically the same phenomena are occurring as in the process which is slightly active, shown in Chart 3, but that the area of involvement is much greater; consequently the temperature is higher and the symptoms on the part of the patient are more pronounced. In temperatures which are supposed to show the effect of associated bacteria, the so-called "mixed infections," we note particularly the wide daily range, starting very low in the morning and rising to a very high point in the afternoon, as in Chart 5. Here, also, autolysis must be an important factor. That we can have a continuously high fever in tuberculosis without caseation is well known. Chart 6 is the chart of a patient suffering from an acute miliary tuberculosis which was engrafted on a chronic process, and Chart 7 an acute miliary process of sudden onset, the patient dying in three weeks' time.

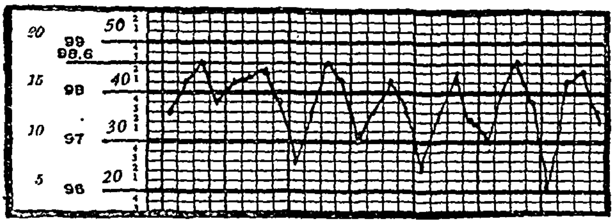

Chart 1

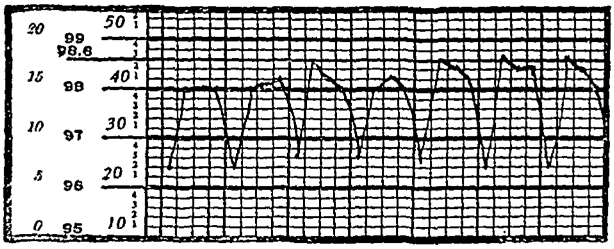

Chart 2

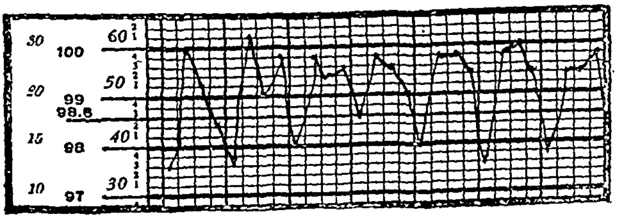

Chart 3

Chart 1.—Fever curve of chronic fibroid tuberculosis.
Chart 2.—Fever curve of quiescent tuberculosis, ulcerative type.
Chart 3.—Fever curve showing activity in tuberculosis of chronic ulcerative type.

A glance at the accompanying charts, bearing in mind the associated pathology, shows clearly that the greater the necrosis, that is, the greater the enzyme action, the higher the fever. Study of the clinical aspects of tuberculosis associates not only the rise of temperature, but also many of the most distressing symptoms and complications with the necrosis. How much these are due to bacterial toxins and how much to enzymes and the products of their action remains to be determined.

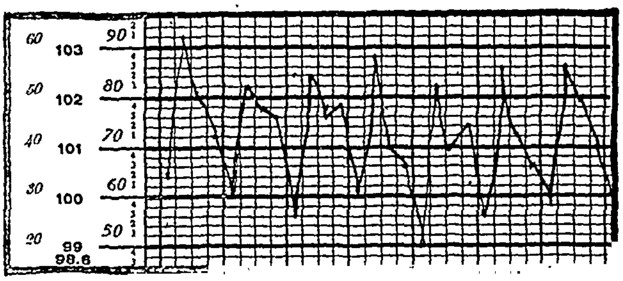

Chart 4

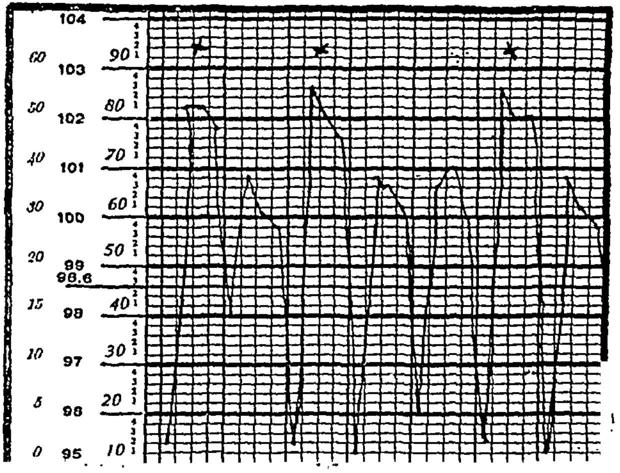

Chart 5

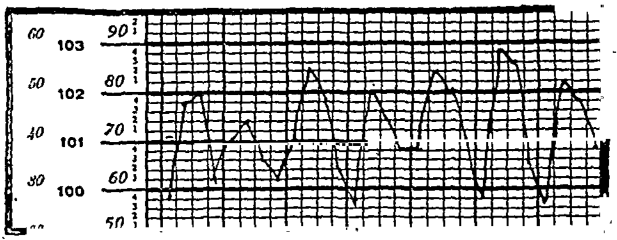

Chart 6

Chart 4.—Fever curve of caseating pneumonic type.
Chart 5.—Fever curve of mixed infection, also showing the effect of baths in raising temperature. Crosses indicate days baths were given.
Chart 6.—Fever curve of acute miliary tuberculosis engrafted on a chronic process.

In our discussion of the cause of fever we are forced to acknowledge that we are unable to explain exactly how bacteria and their toxins and the enzymes and the products resulting from their action produce fever; but there are such wide gaps in our understanding of its pathology which remain to be filled in by further study that we are lost in a maze of uncertainty. Krehl[7] considers that the cause of fever "lies in the mechanism which regulates heat loss," and expresses the belief that

---

[7] Krehl: Pathologische Physiologie, 1906, p. 392.

"the heat in fever is produced in such a manner that it does *not* furnish the *normal* stimulus to the mechanism that increases heat loss." Roger[8] expresses the opinion that "fever is a morbid state resulting from the exaggeration of the chemical processes concerned in the production of animal heat." He looks on the rise in temperature as being due to the reaction of the organism *against* bacteria, their products, and other substances among which we would place enzymes and the products of their action; and, contrary to Krehl, he says:

> Thus fever is due to increased chemical activity, whether or not there be a comitant departure from the normal evolution of matter. Dissipation of heat in fever is more-marked than under normal conditions, but excess in the production of heat is still more marked, hence the relative retention of heat and rise of temperature.

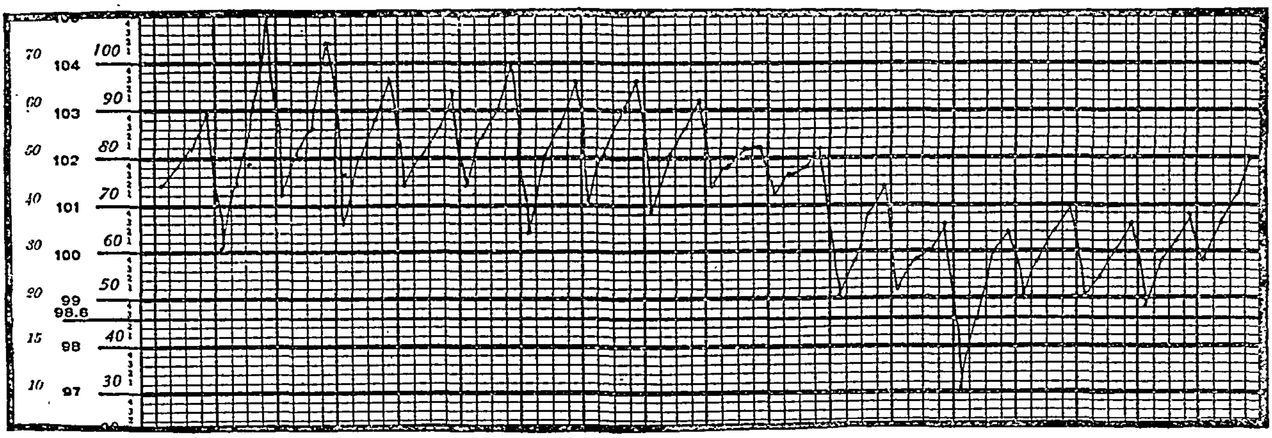

Chart 7.—Acute miliary tuberculosis, with fatal issue in about three weeks.

If we assume that the normal rectal variation of daily temperature for the healthy adult is about 1.4 F., as shown in the accompanying Chart 8, after Jürgensen, and compare this with the various charts of tuberculous patients shown above, we note that when inflammation is present, the temperature as a whole rises, the variation remaining about the same for the most part except in a certain type of cases, notably those which we have been wont to designate as "mixed infection." The height of the curve seems to depend on the amount of chemical changes present and the powers of the organism to react. In the so-called "mixed infection" curves, there are two tendencies present. Careful study of toxins shows that *their tendency is to lower temperature* in large doses, while the tendency of the body cells is to react with an increase of temperature. In those cases which we are wont to designate as "mixed infection," the amount of toxic products set free seems to be very large; consequently if the patient's powers of reaction are still good, *the daily range of temperature is much increased.* We note the same wide range of temperature during the last days of life in cases in which we find post mortem, evidence of a recent wide-spread destruction of lung tissue. I believe we are justified in attributing it largely to absorption of the products resulting from enzyme action. While under ordinary circumstances in quiescent and slightly active tuberculosis the normal daily variation of 1.4 F. is fairly well maintained, *in these conditions there is a wide departure.* From the excessively large dose of toxins the temperature is markedly depressed, reaching at times several degrees below normal. If the patient's powers of reaction are good this depression is followed by a high curve. In Chart 9 it will be noted that this range in one day amounted to more than nine degrees. As the patient's

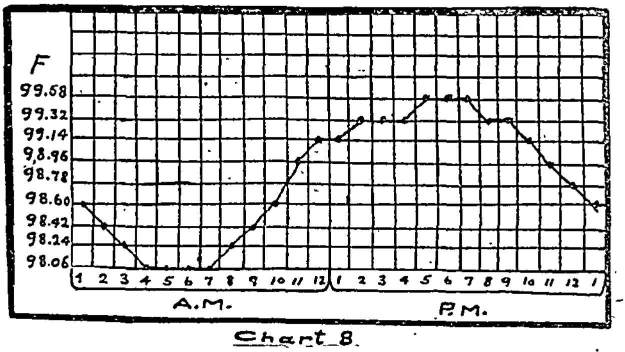

Chart 8.

Chart 8.—Showing daily course of rectal temperature under normal conditions (after Jürgensen).

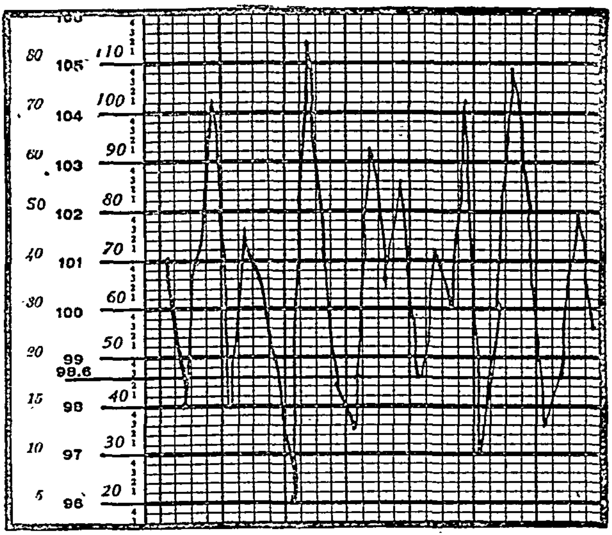

Chart 9.

Chart 9.—Fever curve showing rapid disintegration of lung tissue, absorption of large quantities of toxins, body cells still able to react.

---

[8] Roger: Infectious Diseases, trans. by Gabriel, Lea & Co., 1903, p. 333.

power of reaction wanes, the temperature fails to reach the high points. It falls because of the toxic action and the inability of the body cells to react.

While we look on the three factors discussed above as being the primary causes of the elevations in the general temperature curves in tuberculosis, there are many factors which contribute to the variations found in these curves, some of which are subjective and others objective. Physical exertion is one of the most common causes of elevation in the temperature curve, Chart 10. In Chart 11 the effect of an overexertion may be seen in a patient who was recovering from a chronic temperature. The effect of this overexertion was never overcome. Mental perturbation is also frequently followed by variations in the temperature curve. Thought, reading, excitement, worry, joy, disappointment and fear all have their effect. The effect of worry is well shown in Chart 12. This patient was disturbed over the illness of her mother and her temperature assumed a higher plane until the mother was better. The effect of a large meal is often seen. Intercurrent complications, such as constipation, indigestion, colds, pleurisy, toothache, as well as the more serious ones, such as pneumonia, pneumothorax, and emphysema, all affect the regular curve. The effect of indigestion and constipation are often shown in a rise of temperature. Chart 13 shows an acute inflammation in a tuberculous process in the lung with probable expulsion of the contents of a softened tuberculous mass. The rise was accompanied by increased cough and expectoration.

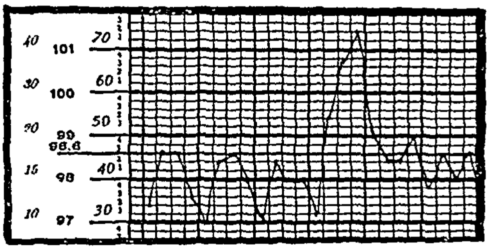

Chart 10

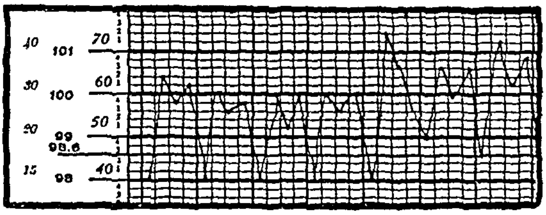

Chart 11

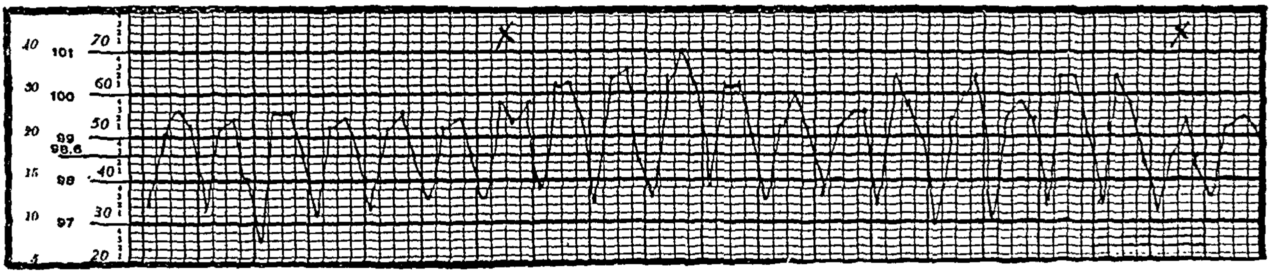

Chart 12

Chart 10.—Fever curve showing effect of overexertion in a chronic inactive case. Prompt return to normal.

Chart 11.—Fever curve showing effect of overexertion in a chronic active case. Failure to return to normal.

Chart 12.—Fever curve showing the effect of worry in patient suffering from chronic active tuberculosis. On the day marked by first star patient received word that her mother had cancer; the second star shows results of news that the diagnosis was incorrect—prompt drop in fever.

Aside from these influences *within* the patient, there are some without which affect the curve materially. It must be remembered that one cause of fever is lack of dissipation of heat. Therefore, it can readily be seen how thermometric and barometric changes affect the loss of body heat and consequently the temperature curve. From Chart 14 the effect of thermometric change is very plain. The low temperature on cold mornings has long been recognized. Another fact observed is that often a very annoying variation in temperature is produced by baths, the regular cleansing bath being followed in some patients regularly by a rise in temperature no matter how carefully the bath is given, as shown in Chart 5.

It will now be readily understood that there are so many influences which affect the temperature in the tuberculous patient that we are at times completely lost in our attempt to assign the proper cause for variations which occur. As a result of this confusion, the physician is at a loss to know the correct interpretation and the proper treatment to employ.

There has been too much of a tendency to deal in generalities in discussing the fever in tuberculosis, and the factors which produce it. It is commonly believed that every temperature above 100.4 is due to mixed infection. It is likewise believed that every patient who is having a high temperature is saturated with tuberculin which is circulating through his tissues. Nearly every rise in temperature which causes a temporary rise in the general curve is interpreted by many observers to mean an auto-inoculation of tuberculin. A moment's consideration of the underlying pathology and the conditions and influences surrounding the individual patient, however, will readily demonstrate that such general statements have no place in dealing with this disease. It is important to grasp these facts, for they have their bearing on the treatment of tuberculous fevers. At best, it will be seen that treatment of these conditions is a very complex proposition. It is especially necessary to interpret carefully the temperature curve when tuberculin is employed therapeutically.

Many of the contributing causes of fever discussed above can be avoided, while some, such as those depending on thermometric and barometric conditions, must be endured. Overexertion can be avoided by a little care. The effect of mental activity can, as a rule, be overcome. Reading, thinking and excitement are largely within the power of the patient to control, while worry and disappointment can usually be avoided to a large extent if the patient and physician are in thorough sympathy with each other and are cooperating as they should. Most of the complications which arise cannot be relieved at once. Some cannot be relieved at all. Some must run a regular course; but close personal medical supervision favors accuracy of diagnosis and affords rapid relief from many of them.

The relief of the fundamental causes of fever as described above is a very difficult matter and one which will often tax the patience of the physician and patient unless both are blessed with an unusual amount of optimism.

There are certain established therapeutic principles which may be followed no matter what the cause of the fever may be; nevertheless, there are certain fundamental facts which have been continuously overlooked that must be understood if we are going to attack this condition with any degree of intelligence.

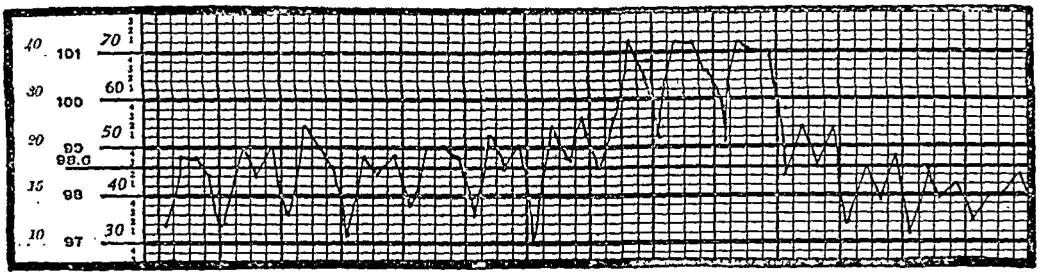

Chart 13.

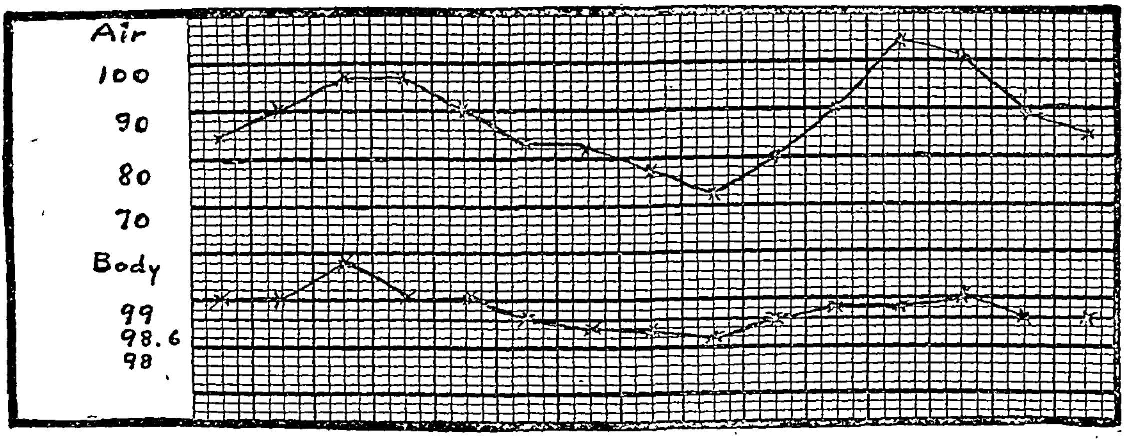

Chart 14

Chart 13.—Fever curve showing acute inflammation with expulsion of tuberculous material in a chronic inactive process.

Chart 14.—Fever curve showing the influence of the atmospheric temperature on the body temperature. Lower curve, body temperature; upper curve, air temperature.

Carefully regulated hygienic living in the open air with rest for both the body and mind, food, selected according to the patient's digestive capacity, and various hydrotherapeutic measures may be advantageously employed in all cases. These measures act by improving the general nutrition of the patient so that he may withstand the effects of fever better, also by lessening some factors which increase heat production, and by bringing about conditions which favor heat loss. None of these measures has any direct effect on the bacteria and their toxins and the enzymes and the products resulting from their action which we have mentioned above as the primary causes of the fever. The primary causes must be combated by specific measures. We know that specific antibodies are formed within the body, which bring about the natural healing of specific infections. This has led to the specific treatment of many of the infectious diseases whose causative germ has been discovered.

Tuberculin has partly won for itself, through probably the most severe trial to which a remedy has ever been subjected, the right to be considered as a specific against tuberculosis. Vaccines made from dead culture of various bacteria which we find associated with tuberculosis have proved to have specific action against pathologic conditions which are produced by their own strain. In spite of these specifics against the bacteria there are many foci which we cannot heal, many temperatures which we cannot lower in advanced tuberculosis. One reason for this is inexact diagnosis; another, that we have no specific against the enzymes and the products resulting from their action. Would it not be profitable to attempt the production of specific remedies against the body enzymes and the products of their action? This would not seem impossible, for Jochmann and Kantorowicz[9] and others have demonstrated antienzyme in the blood. Our conception of the machinery of immunity is such that we are led to believe that the cells of the body must produce substances which protect the body from these enzymes and the broken-down tissues, which are the products of their action. Our conception is that in these advanced cases, the body cells are constantly producing substances which protect the body against the tubercle bacillus and its toxins and the enzymes and the products of their action; and, where other bacteria are associated in the process, against these. Our rational therapy will be effective only as it aids and supplements these natural processes.

---

[9] Jochmann and Kantorowicz: Ztschr. f. klin. Med., 1908, lxvi, 153.

This brings us to the discussion of whether or not tuberculin is applicable in the treatment of fever patients. From a long clinical experience including several hundred fever patients, I am convinced that tuberculin when properly administered is of great value in these cases. The requirements that I would make are a thorough acquaintance with the use of tuberculin, close personal observation, such as is available in an institution, and the exercise of care and judgment in the administration of the remedy. I have frequently seen temperatures of 101 and even higher, which were reduced by tuberculin, the fall being coincident with each dose, so as to leave no room for mistake as to the cause. In such instances I have been wont to consider the bacillus and its toxins the chief cause of the rise. On the other hand, I have seen temperatures of less than 100 as well as high ones which seemed entirely uninfluenced by tuberculin. Such, I believe, are those in which absorption of the toxins of other micro-organisms or of the disintegrated tissue are the main cause.

The reason usually assigned for the non-employment of tuberculin in fever is that the patients are already saturated with tuberculin. That this is not necessarily true can easily be established. In the first place, it is probable, as mentioned above, that tubercle toxins are not the chief factor in the production of fever. Again, as noted in a previous paper,[10] if the system of the fever patient were completely saturated with tuberculin, all foci would be the seats of focal reactions which could be easily detected in all visible tuberculous processes such as ulcerations of the larynx and pharynx. But this is not true. Such processes show the focal reactions, however, after injections of therapeutic doses of tuberculin, which, in amount, are short of a fever reaction. Still again, if this were true, all tuberculous foci would break down as a result of the constant focal reactions. Furthermore, if the patient were saturated with tuberculin, the temperature would fall; for excessive doses of toxins would overcome the patient's reactive powers and cause a drop in temperature.

The reason that tuberculin should be employed in the treatment of patients suffering with fever is the same as that for employing it in non-febrile cases; that is, for its effect on the healing of the purely tuberculous processes. There are these in all cases. It must not be supposed that when a patient has an elevation of temperature the entire portion of the lung that is involved is producing the fever. On the contrary, the area which is the seat of activity is often quite small. I have seen temperatures of from 101 to 105 associated with the formation of small ulcers in the larynx and pharynx where I could feel reasonably sure that these small foci were the cause of the temperature (see Chart 15). The probability of this is strengthened by the elevation of temperature which often follows small abscesses. If the correct administration of tuberculin will not cause an intense and dangerous focal reaction, and when intelligently administered, it will not, then we can see that it can be employed in fever cases with the same advantage to the patient as in non-febrile cases. Of course this statement implies that the patient's reactive powers are still good, and capable of responding in the production of antibodies. Personally I have seen many lungs and portions of lungs which were the seat of recent infection clear out under tuberculin, while the patient ran fever and formed cavities in other portions of the lung. Whoever undertakes the treatment of such patients, however, must not expect tuberculin to do the impossible. He must be satisfied with what it is able to do and not look for miracles. It might do all that it can do and the temperature still persist.

My purpose in this paper is to show the actual as well as contributing causes of fever in tuberculosis and to show what measures may be employed against them and at the same time indicate why we so often fail.

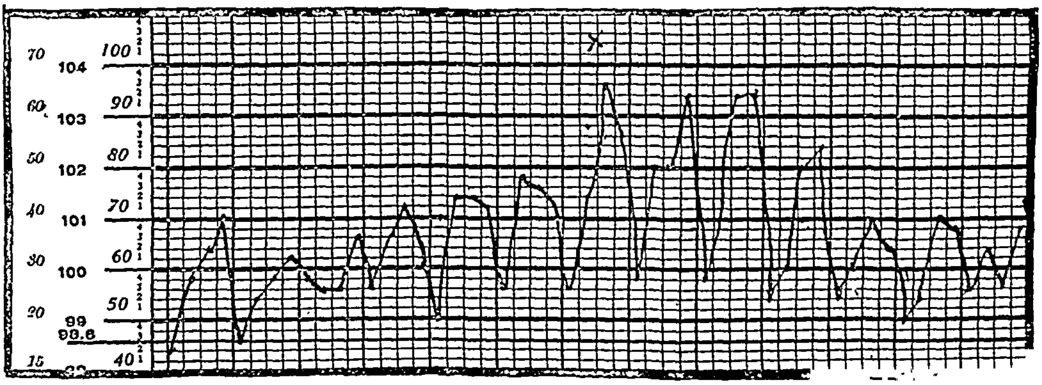

Chart 15.—Fever curve showing elevation in temperature produced by a small ulceration of the pharynx.

ABSTRACT OF DISCUSSION

Dr. Edward F. Wells, Chicago: The temperature curve in tuberculosis is a matter of great importance from many points of view. Several years ago I had occasion to observe closely a number of cases of early tuberculosis, in which it was clearly shown that a slight or moderate rise of temperature, continuing for about a week, with some local and general symptoms, would be followed by a normal temperature and subsidence of symptoms for about a month. These cycles, each somewhat more pronounced than the one preceding, were repeated with considerable regularity. These observations were published at the time, and my only object in again calling attention to them is in relation to the practical bearing which they may have on diagnosis by the tuberculin reaction, when the agent is given hypodermically. It is clear that should the administration be made at the inception of one of the febrile periods the height to which the temperature might rise is not a correct measure of the reaction.

Dr. Norman Bridge, Los Angeles: I should like to compliment Dr. Pottenger on the ingenious explanation made regarding the origin of fever in tuberculous patients. I think that he is probably correct. I should like to enter a protest, however, against some of his declarations in regard to the use of tuberculin. He says: "Tuberculin, when properly used, does a great deal of good." I sincerely hope that is true. But I do not believe there is anybody living who can state positively that it is true. I certainly wish that it might be true. To my mind there is no sufficient evidence of the great value of tuberculin. Many have claimed that there is positive evidence of the value of tuberculin; in times past there has been no doubt a great deal of injury done by the use of excessive doses of this agent. Those who are now using this agent should be cautioned. I am positive that it does but a small amount of good compared with the good that results from general hygienic treatment.

---

[10] Pottenger: Tuberculin as a Therapeutic and Diagnostic Agent, in Hare's Modern Treatment, 1910, i.

With regard to Dr. Pottenger's other statement about the person who knows how to use tuberculin, I should like to enter a gentle and friendly protest, because no man living knows absolutely how to use tuberculin. In my judgment the only real and safe way is to use it in doses so small that it can do no harm; it should be given at intervals so long that no harm can come from the frequency of its administration. Time should be allowed between doses to learn if any harm results from the tuberculin. One should endeavor to learn exactly just the amount of tuberculin to give and the intervals between doses. One cannot generalize from the results obtained in a few cases; one can only generalize from the observation made of a large number—hundreds—of cases of those who have been treated side by side with and without tuberculin. And there are but few men who have had experience enough and have carried their parallel observations far enough and carefully enough to enable them to speak with authority. However, I hope the profession will continue to use tuberculin. I am in the habit of giving 1/500 mg. once a week only. I think that no harm can result from such small doses, but that some benefit will result in some cases. But that the giving of this agent in any case will be productive of great good, I do not believe.

Dr. Frank Billings, Chicago: I supposed that the question of the fever in tuberculosis had been pretty well settled and that it was due to toxins. Last year while in England I enjoyed a visit with Dr. Paterson, who explained his method of treating tuberculosis by auto-inoculation. Of course I knew something of it before my visit and had seen some of the results of its employment here. If I understand Dr. Pottenger correctly he does not believe that tuberculin in any dose produces or reduces temperature. I simply rise to ask his opinion regarding this point. Were these patients afflicted with the miliary type or the acute ulcerative type?

Dr. Philip King Brown, San Francisco: I also rise to ask a question. I do not understand what Dr. Pottenger means by autolysis in fever in tuberculous patients. This is rather a technical term and difficult to follow in connection with what he says regarding fever in tuberculosis. I have labored under the impression that there was a toxic agent at work which produces fever in this disease. As a matter of fact Dr. Vaughan made some interesting experiments, reported before the Association of American Physicians last summer, on the protein reaction as a cause of fever in bacterial diseases. The animal experimented on could be caused to have temperature of any type by the introduction of some protein substance subcutaneously. Most of the work was done with egg albumin. Dr. Vaughan explained the resulting fever as depending on some anaphylactic action. The extent of this reaction depended on the frequency and the amount of the protein introduced. I should like Dr. Pottenger to state whether he had gone into this carefully and what he means by stating that toxins do not cause or increase the fever.

Dr. C. F. Tenney, Toledo, O.: I have given tuberculin with beneficial results when the temperature has not been above 99.4 F. If the temperature is higher than 99.4 F. I believe that rest is indicated. I should like to ask Dr. Pottenger why he gave tuberculin when there was a high temperature.

Dr. F. M. Pottenger, Monrovia, Cal.: If I had been permitted to read my paper in full the various questions asked me would most probably have been satisfactorily answered. Dr. Bridge has certainly been unfortunate in his experience with tuberculin. I wish to state emphatically that I do not agree with what Dr. Bridge has stated regarding the use of tuberculin. The intelligent use of tuberculin, like all other remedies, consists in individualization, suiting the dosage to the individual patient under treatment. When one uses tuberculin after the manner described by Dr. Bridge, unsatisfactory results are sure to follow. One does not operate in any two cases of appendicitis alike, or treat any two patients with typhoid fever the same, neither does one administer digitalis nor strychnin alike in all cases, and yet Dr. Bridge would have us give 1/500 mg. of tuberculin once a week to all patients who are treated with tuberculin. I would not want to have it go out from this meeting that this is the proper use of tuberculin. Such a method is erroneous and incapable of producing the best results.

For fifteen years I have preached the importance of individualization in the use of tuberculin. To give so many drops of this or that dilution at certain intervals cannot be expected to be productive of much good. One must bear in mind what tuberculin is and what it is supposed to do. Unless great care is used in its administration much harm may result, but when used intelligently good must just as necessarily follow.

When tuberculin is being used all other measures which are recognized for building up the patient should be employed.

Tuberculin can be employed as intelligently as any other remedy that we have. We cannot give a satisfactory explanation of the action of many of our remedies, but this must not deter us from using them according to our clinical observations. Small doses of tuberculin are not necessarily conservative. The proper method of using tuberculin is to give the right dose at the right time. If one starts in with small doses and increases them gradually, the patient will soon bear the doses without danger of reaction. In my private work I always have more than 100 patients under treatment with tuberculin and yet I rarely have a rise of temperature of more than ½ degree as a result of its administration. I agree with Dr. Bridge that no one knows exactly how this remedy acts. Who knows all about digitalis or strychnin? Our lack of knowledge, however, does not deter us from producing good results.

Dr. Billings speaks of the work of Paterson. I am familiar with Paterson's observations and think he is doing an admirable work, but it must not be forgotten that he is dealing exclusively with early inactive cases. The patients of whom I am speaking are almost all advanced and suffering from active tuberculosis. Rest is an absolute essential in the treatment of all cases of active tuberculosis. I always enforce it if the temperature is above 100, and in many cases in which it is under, if other conditions would indicate it.

Regarding Paterson's interpretation of every rise of temperature following exertion, as an auto-inoculation, I think there is some room for question. I do not believe that all these can be ascribed to an auto-inoculation of tuberculin. There are other factors which come in.

Regarding the effect of large doses of toxins in reducing temperature, many experiments have been performed in which staphylococci and streptococci as well as tuberculin have been employed, showing that following the injection the temperature was markedly decreased, and if the dose is fatal the animal dies with subnormal temperature.

In reply to Dr. Brown regarding enzymes and autolysis, I would refer him to the excellent work done by Frederick Muller, Ascoli and Bezzola, and Opie. From my clinical experiments I believe that enzymes and the products of autolysis are very important factors in the production of fever and that they deserve very careful study.

Significance of the Death-Rate.—The general death-rate is the most important single piece of evidence of the health of a place, says W. S. Rankin in *Bulletin of the North Carolina Board of Health*. Just as general vitality in an individual is counted in the rise and fall of the pulse wave, so the general vitality of the body politic is counted in the rise and fall of its death-rate. At first glance this symptom might appear as misleading. In certain cases attention might be called to the fact that diseases like hookworm and malaria rarely terminate fatally. This seeming inaccuracy disappears when we recall that diseases, not of themselves terminating in fatal issue, tend to that end by lowering the general resistance of the body to death-dealing germs, and so indirectly and ultimately register their existence in increasing death-rates.

EXPERIMENTS ON THE RELATION OF THE THYROID TO DIET *

REID HUNT, M.D.
Professor of Pharmacology, U. S. Hygienic Laboratory; P. H. and M.-H. S.; Member of the Council on Pharmacy and Chemistry, American Medical Association
WASHINGTON, D. C.

From the results of some recently published experiments[1] I suggested the hypothesis that certain diets have specific effects on the activity of the thyroid gland; the results of these physiologic experiments were, in part, in accord with histologic studies made some time ago by Watson. This hypothesis was based largely on the fact that certain diets have an effect on the resistance of animals to certain poisons similar to that caused by the administration of thyroid, and, further, on the observation that the effect of the administration of iodin to animals is, in part, determined by the character of the diet; it was held that the latter determined the ability of the thyroid to combine with the iodin.

I have recently endeavored to put this hypothesis to further experimental test. The results are in entire harmony with the above views, although I do not consider the experiments sufficiently numerous or varied to be entirely conclusive.

METHOD

The method was the same as that used in the preceding experiments, and is based on the increased resistance which mice show to acetonitril after the feeding of thyroid.

It had been found in earlier work that the resistance to this poison was much greater in the case of mice which had had a diet of oatmeal, or of oatmeal and liver, than in the case of those which had had a diet of eggs, crackers, and milk.

The effect of these diets on the resistance to the poison was now determined in mice from which the thyroid glands had been removed.

In the first series the thyroids were removed from a large number of young mice. In many cases the operation was not satisfactory, portions of the thyroid undoubtedly being left. A considerable number of the animals died, many of them in tetany. The survivors were placed on the exclusive diets of eggs or of oatmeal for thirty days, when their resistance to acetonitril was determined. Table 1 shows the results:

TABLE 1.—FATAL DOSE OF ACETONITRIL IN MG. PER GM. OF MOUSE

	Controls.	Thyroidectomized.
Egg-fed	0.40-0.43	0.44
Oatmeal-fed	0.85	0.63

The normal mice fed on oatmeal were, as usual, more resistant to the poison than the normal mice fed on eggs. Thyroidectomy had had no effect in the case of the egg-fed mice, but had distinctly lowered the resistance of the oatmeal-fed mice. This result is in harmony with the hypothesis that the high resistance of the oatmeal-fed mice is due in part, but only in part, to an effect of this diet on the thyroid.

In the second series, young mice were kept for a few weeks on diets of oatmeal and liver, and on crackers, milk, and eggs. The thyroids were then removed from a number of each group and the same diets continued for twelve days. The thyroids of the oatmeal and liver-fed group were invariably very large and vascular, bleeding readily; those of the other group were exceedingly small and pale. About 80 per cent. of the oatmeal-fed mice died, most of them in tetany; 33 per cent. of the other group died. Twelve days after the operation the fatal dose of acetonitril was determined with the results shown in Table 2.

TABLE 2.—FATAL DOSE OF ACETONITRIL IN MG. PER GM. OF MOUSE

	Controls.	Thyroidectomized.
Crackers, milk and eggs	0.15	0.17
Oatmeal and liver	4.3	2.2

Thus the controls which had been kept for several weeks on the oatmeal-liver diet were far more (almost thirty times as) resistant to the poison as those which had been on the diet of crackers, milk, and eggs. Thyroidectomy had little effect on the resistance of the latter; it lowered that of the former by about one-half.

The next series is of interest from another point of view. A large number of young mice were fed for thirty days on oatmeal, crackers and eggs, before the removal of the thyroids. This diet was selected on the belief that the mice receiving it would have neither the large and excessively vascular thyroids of those fed on oatmeal and liver, nor the extremely small glands of those fed on crackers, milk, and eggs. As a matter of fact the thyroids were of medium size and easily removed. The fatal dose of acetonitril for the controls of this series was 1.8 mg. per gram (as compared with 4.3 for the oatmeal-liver-fed mice, and 0.15 for those of the preceding series fed on crackers, milk, and eggs).

The thyroidectomized mice and a number of the controls were then given crackers containing 0.1 per cent. potassium iodid for ten days, when their resistance to acetonitril was determined; the results shown in Table 3 were obtained.

TABLE 3.—FATAL DOSE OF ACETONITRIL IN MG. PER GM. OF MOUSE

	Controls.	Potassium Iodid.
Normal	1.8	1.8
Thyroidectomized	...	0.7

As a rule the administration of potassium iodid (and many other iodin compounds[2]) to mice increases their resistance to acetonitril (increased activity of the thyroid); that it did not do so in this case was probably due to the inability of the thyroid, for some reason, to combine with the iodin. The thyroidectomized mice withstood less than half as much acetonitril as did the controls. This I believe to be due to the absence of thyroid secretion.

The above experiments shows that the high degree of resistance of mice to acetonitril caused by certain diets is due in part to the activity of the thyroid gland. In cases in which the thyroid was apparently not very active (as judged by its small size and the low resistance to acetonitril), its removal had no effect on the resistance to the poison; this was the case with the mice fed on eggs, and crackers, milk and eggs.

I had found in earlier experiments that removal of the thyroid did not have a constant effect on the resistance of guinea-pigs to acetonitril; Carlson and Woelfel state that they obtained similarly negative results with rats and mice. The above considerations seem to sufficiently explain such negative results; the latter do not at all invalidate the conclusion that the acetonitril test is a test for thyroid activity, at least when the latter is exaggerated.

---

* Read in the Section on Pharmacology and Therapeutics of the American Medical Association, at the Sixty-Second Annual Session, held at Los Angeles, June, 1911.

[1] Bull. 69, Hyg. Lab., P. H. and M.-H. S.

[2] Hunt and Seidell: Jour. Pharmacol. and Exper. Therap., ii, 15.

In other experiments the thyroids of the mice (or of other animals) which had received special diets were removed and fed to other mice; the resistance of the latter to acetonitril was then determined. There is obviously more than one possibility here: a thyroid might be very active but, owing to conditions favorable to secretion, contain at one time little of the secretion itself; this seems to be the case, for example, with the thyroid in exophthalmic goiter. Or the thyroid might be very active and also contain a considerable amount of the secretion. Both of these possibilities seemed to be realized in my experiments; with some diets the greater the resistance of the animal to the poison the less was the protective action of its thyroid when fed to other animals. With other diets the reverse occurred; the greater the resistance of the animal the greater the activity of its thyroid. The following is an example of the latter class of experiments:

One group of mice was kept for several weeks on a diet of crackers, milk, and eggs; the fatal dose of acetonitril was 0.1 mg. per gram of mouse. Another group was kept on a diet of oatmeal and liver; the fatal dose of acetonitril was 0.33 mg. per gram. The average weight of the mice of the former group was 19.81 gram; that of the latter 19.52 gram. The thyroids were removed from the two groups, dried, and fed to other mice so that each of the latter received one-half of the thyroid of a mouse per day. After ten days the resistance of these mice was determined: The normal (control) animals died from 0.7 mg. acetonitril per gram; those receiving the thyroids of the group fed with crackers, milk, and egg died from 1.6 mg., those receiving the thyroid of the oatmeal-liver-fed group died from 2.3 mg. Thus there was a parallelism between the resistance of the mice and the activity of their thyroids.

Similar results were obtained with rats. In these animals the administration of thyroid causes a lowered resistance to acetonitril; hence a low degree of resistance suggests an active thyroid and vice versa. In one series of experiments rats on a certain diet died from 1.2 mg. acetonitril per gram; rats on another diet recovered from 3.3 mg. per gram. It was suspected that the thyroids of the former would be found more active than those of the latter when fed to mice; this supposition was confirmed: Mice receiving the thyroids of the former group of rats recovered from 3.5 mg. acetonitril per gram; mice receiving the thyroid of the rats of the second group died from 2.5 mg. per gram. Thus here again there are two distinct lines of evidence for the view that the diet has an effect on the activity of the thyroid.

TABLE 4.—RESISTANCE TO ACETONITRIL OF MICE ON SPECIAL DIETS WITH FEW AND MANY OFFSPRING

First Four Months' Diet.	Oatmeal and Liver.	Crackers, Milk and Eggs.	Corn-Meal and Milk.
No. of young born..............	0	97	69
Fatal dose of acetonitril in mg. per gm. of mouse............	....	About 0.23	About 0.55

Second Four Months' Diet.	Crackers, Milk and Eggs.	Oatmeal and Liver.	Corn-Meal and Liver.
No. of young born..............	59	28	41
Fatal dose of acetonitril in mg. per gm. of mouse............	0.27 to 0.45	2.3 to 4.4	2.5 to 4.5

Finally, attention may be drawn to an interesting parallelism between the effect of certain diets on the resistance of mice to acetonitril, and their effect on the reproductive activity of the mice. Four groups of mice, each consisting of three females and one male, were fed on the diets named below for four months; at the end of each month the young were removed and their resistance to acetonitril determined. After four months the diets were changed. Table 4 shows the results.

Thus with these special diets the young of the mice producing the most offspring were the least resistant to the poison: the young of those producing the fewest offspring were the most resistant. Whether this is true with other diets has not been determined. In an earlier paper I showed that in many cases there is a parallelism between the rate of growth and the sensitiveness to acetonitril: a similar parallelism is seen here between the sensitiveness to this poison and the reproductive activity. We are now conducting experiments to determine if there is any relation between the reproductive activity and the rate of growth (as determined by special diets) and the inoculability of carcinoma.

An interesting fact shown in the above table is that the diet seemed to have a long-continued effect on the reproductive activities; mice taken from a mixed diet (of bread and oats) and placed on one of oatmeal and liver produced no young in four months, whereas mice which had received for four months a diet of crackers, milk, and eggs, continued fairly productive when placed on a diet of oatmeal and liver.

SUMMARY

These experiments afford additional experimental support for the view that certain diets have specific effects on the thyroid glands of some of the lower animals. It is probable that analogous relations hold for human beings. Although it is possible that the effects differ in different classes of animals it would be interesting to determine if, in cases of hypothyroidism, the administration of oatmeal and liver, for example, would have a favorable influence, and if the withholding of them from patients with hyperthyroidism would be found advantageous. The most promising class of cases for such observations would be the mild degrees of thyroid derangement, such as those recently described by Kocher in his Nobel lecture.[3]

ABSTRACT OF DISCUSSION

Dr. Theodore G. Davis, Los Angeles, Cal.: This would suggest a practical point; that is, the fact of the thyroid gland antidoting the drugs having benzoyl and anilin bases, as acetanilid and many others derived from that group; as the trinitril is the test for acetanilid and similar compounds.

---

[3] The results of the experiments described above are in harmony with the interpretation I have hitherto placed on the acetonitril reaction, viz., that it is a test for the internal secretion of the thyroid; the results obtained by feeding the thyroid gland itself I have interpreted as being due to its containing some of the internal secretion.

Trendelenburg (Biochem. Ztschr., 1910, xxix, 396) has interpreted the results in a different manner. He fully confirmed my results that the administration of thyroid increases the resistance of mice to acetonitril; but he also found that the blood of thyroidectomized cats protected mice against this poison. He believes that in the absence of the thyroid, toxic substances accumulate in the blood, and that these cause the reaction; he also believes that these substances, when absorbed by the thyroid, cause the latter to give the test. Trendelenburg did not test the resistance of the thyroidectomized cats to acetonitril.

These results show how complicated the problem is. It would be useless to indulge in much speculation without further experiments, but it may be suggested that, assuming the processes to be the same in mice and cats, there is a formation of protective substances in the absence of the thyroid, but that these are unable to protect the animal producing them without the interaction of the thyroid gland itself. Or, possibly, in Trendelenburg's experiments thyroidectomy had caused changes in the composition of the blood so that this contained protective substances analogous to those contained in oatmeal, liver, the prostate, etc., or substances which stimulated the thyroids of the mice to increased activity; for while my experiments show that the effect of oatmeal and liver is in part due to an effect on the thyroid they show equally plainly that other factors are involved.

There are no contradictions in the experimental results of Trendelenburg and myself, and there may also be no real contradiction in our interpretation of them.

A PLEA FOR MORE DIRECT METHODS IN DEALING WITH GASTRIC ULCERS AND CANCER *

R. C. COFFEY, M.D.
PORTLAND, ORE.

The strides in gastric surgery during the last ten years have been very remarkable. Originally the first aim of the surgeon was to diminish the mortality of disease with the least mortality resulting from the means of relief, but as Dr. Charles Mayo says, the modern requirement is the relief of morbidity. In other words, the patient not only demands relief from the immediate conditions with a low mortality, but he has a right to expect symptomatic relief and immunity from sequelæ. I dare say that the first thought of most, if not all operators in the early development of the surgical treatment of callous gastric ulcer was the excision of the ulcer. The first stomach operation of any kind that I ever attempted was ten years ago, when an ulcer in the posterior wall and lesser curvature, such as shown in Figure 4, was excised. The patient died from faulty technic and I did no more gastric surgery until I learned more of Mayo's work in gastro-enterostomy. It is possible that other surgeons have had similar experiences which have not been reported.

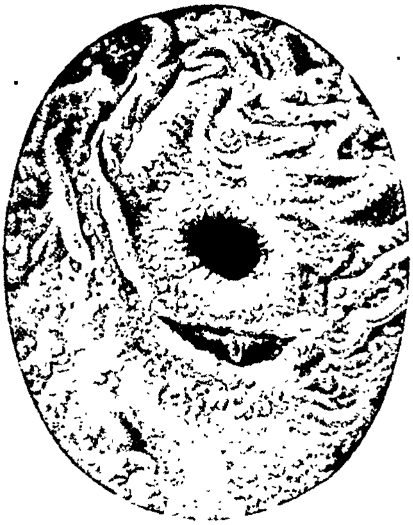

Fig. 1.—Post-mortem specimen of stomach mucous membrane in which is shown a stoma forty-eight hours after a gastro-enterostomy; also a slit in the mucous membrane produced by clamps. Crossing the slit is a vessel which was devitalized by the clamp and which gave way thirty hours after the operation, producing a fatal hemorrhage.

The brilliant work of Mayo Robson, the Mayo brothers, Mickulicz, Moynihan, and others, brought gastro-enterostomy so prominently before the profession and so rapidly reduced the mortality that it became almost the universal operation for gastric ulcer. Soon afterward, however, Rodman ventured to put forth his bold procedure for excising the ulcer-bearing area in the pylorus. The mortality has deterred the majority of surgeons from adopting it, but, as technic has been improving, more and more work is being done along this line. The mortality has been greatly diminished, and, as the reports come in year by year, we learn that many of the ulcers supposedly cured by gastro-enterostomy have been only temporarily relieved, and, in the case of ulcers located at other points than near the pylorus, there has not been even temporary relief in a large percentage of cases; furthermore, the danger of the development of cancer in a callous ulcer is much greater than has been supposed. Gerster[1] makes the following summary on callous ulcer of the stomach:

> During the past year attention has been called by authors, both here and abroad, to the great tendency of callous gastric ulcer to carcinomatous change. Wilson and McCarthy[1] have shown that in 71 per cent. of resections for carcinoma, a preexisting callous ulcer could be demonstrated. This was in a series of 153 cases. At the meeting of the Deutsche Gesellschaft für Chirurgie, in the spring of 1910, Ewald stated, in discussing Payr's report that 26 per cent. of gastric ulcers underwent malignant change, that he considered this estimate far too low. In Germany, the trend of opinion seems to be *developing in this direction. In France* an experience of Tuffier bears out this point. He found an induration of the greater curvature, the size of a nut, with two slightly enlarged lymph-nodes in the great omentum near by. The impression gained was that of a chronic ulcer. It was resected and the nodes extirpated. Microscopic examination revealed a typical callous ulcer, at the base of which a carcinoma was beginning to develop. From this experience he concludes that every gastric ulcer which is solitary, and which is easily accessible, should be extirpated. Many other surgeons have emphasized the impossibility of distinguishing malignant from inflammatory tumors of the stomach by gross examination.
>
> The general trend of opinion seems to be leading to this: that gastric ulcers, situated in the body of the stomach but not yet causing stenosis, are not cured by gastro-enterostomy. Resection, when possible, should be done, not only because the ulcer is not cured by gastro-enterostomy, but mainly because its continued existence is a constant menace as regards the probability of a change to carcinoma.

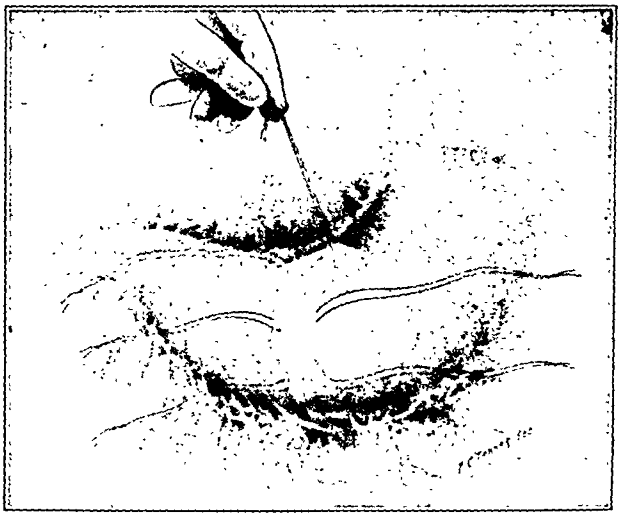

Fig. 2.—Placing traction loops preparatory to opening the stomach for exploration.

Eiselsberg advocates unilateral pyloric exclusion in addition to gastro-enterostomy for ulcers in the pylorus in cases in which the condition of the patient makes resection dangerous or impracticable because of the presence of adhesions; also in those cases in which there is doubt regarding the nature of the tumor existing, and when for apparent reasons one cannot resect. For, as he states, "even a cancer, where it is not subject to the passage of fluid over it, has its growth very much retarded." Eiselsberg further suggests this procedure as a preliminary step to a resection to be carried out on some later occasion.

[1] Progressive Medicine, June, 1911, p. 110.

Mayo, in 1908, made the statement that all callous ulcers not located at or near the pylorus should be excised by direct attack. In 1910, he described[2] a method of transgastric excision of ulcers of the posterior wall which he stated had been previously used by Dr. Pilcher. In the same month I published an article[3] in which another method of excising ulcers of the posterior wall was described, and a number of cases were reported. In this work, clamps were used to protect the field. In the very next case of the kind, after the publication of this paper, it became evident that the ulcerating process had extended beyond the clamps, making it necessary to release the clamps and extend the excision. This allowed a good deal of spilling of stomach contents and among other things revealed the fact that the mucous membrane had been injured by pressure of the clamps. The operation was finally completed and the patient recovered. By this case, however, I learned that the use of clamps is by no means ideal for this excision and further that it is not without danger. Curiously enough, my very next stomach operation—although the simplest kind of a gastro-enterostomy for obstructive ulcer and an ideal case—resulted in the death of the patient from secondary hemorrhage from pressure of the stomach clamps, which case I shall relate in detail:

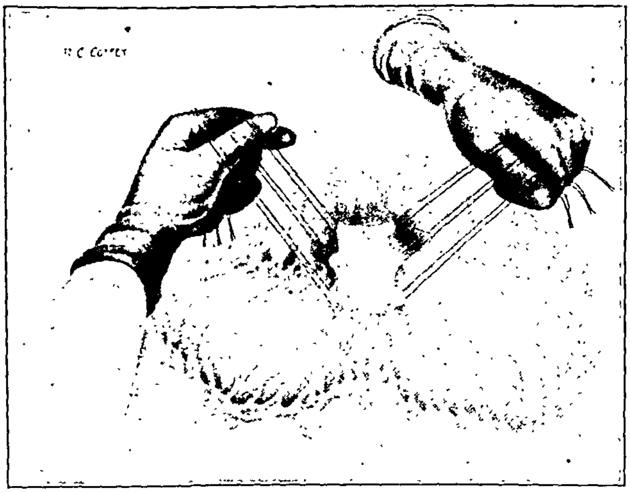

Fig. 3.—Lifting a section of anterior stomach wall by traction loops to permit the air in the stomach to rise to point of proposed incision.

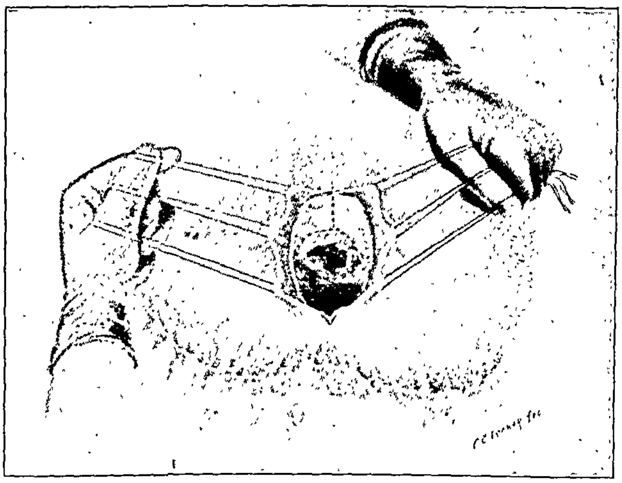

Fig. 4.—The stomach has been incised, exposing the mucous surface. A callous ulcer is seen in the background, while the fluid contained in the stomach may be seen gravitating to the back. Dotted line indicates extent of incision by which this ulcer was removed from the posterior wall and the lesser curvature.

The patient, a male, 50 years of age, had suffered with stomach trouble five years or more. Recently he had rapidly lost flesh and was unable to retain food to any extent. He was referred to me by Dr. Noble Wylie Jones, October 28, with a diagnosis of an obstructive ulcer at the pylorus. The chemical examination of gastric juice showed a slight excess of free hydrochloric acid. October 29, the patient was operated on, a callous ulcer obstructing the pylorus just on the duodenal side was found, and a gastroenterostomy was performed by the posterior no-loop method. The case was an ideal one. The operation was completed in 30 minutes in a very satisfactory manner. The patient was in no way shocked or depressed by the operation and 24 hours after the operation felt well and had a normal pulse and normal temperature. Thirty hours after the operation the nurse noticed an increase in the patient's pulse rate but she was unable to reach me until 36 hours after the operation, or 10 p. m., October 30. At this time the patient's pulse was about 160. I immediately called Dr. Jones and we were unable to make a diagnosis of anything serious. As the patient's wife stated that he had frequently had spells of palpitation of the heart, we tried to persuade ourselves that it was a nervous condition. The patient did not vomit nor was he nauseated. Gas passed from the bowels, but no blood. The temperature was about 100. Therefore we could not believe bleeding was taking place. The patient died at 6 p. m., October 31, 56 hours after the operation. A necropsy was held shortly after death. When the abdomen was opened the intestines were seen to be filled with dark blood. On opening the stomach and examining the ulcer we found that no hemorrhage had taken place from the ulcer. Examination of the stoma, which shows in the center of Figure 1, showed union perfect and no possibility of a hemorrhage. The stomach was practically empty, while the intestines were filled with blood. We realized that death had been caused by hemorrhage but we had not found the point from which the hemorrhage had come, and did not find it until the stomach was entirely removed and washed, when we discovered a slit in the mucous membrane about an inch from the stoma which marked the place where one blade of the clamps had held the stomach. Running directly across this slit in the mucous membrane was a blood-vessel the wall of which had sloughed. The clamp had devitalized the vessel and the gastric juice, being excessive, had undoubtedly digested the devitalized coat of the vessel and the hemorrhage began.

I had previously noted in animal experimentation that the mucous membrane is frequently broken by the clamp in gastro-intestinal anastomosis, but as I had not seen cases of death reported from this cause I inferred that there was practically no danger. The clinical experience just mentioned coupled with what I have seen in animal experimentation has led me to the belief that there have unquestionably been other deaths from the same cause, in which cases the cause has been either undetected or unreported. The function of clamps in gastro-intestinal surgery is three-fold: to hold the viscus for convenient suturing; second, to prevent the escape of large quantities of gastro-intestinal contents; third, to control hemorrhage while the operation is going on. After these experiences I sought to devise a plan by which these ends could be accomplished without the use of clamps and made extensive experimental studies in devising a technic. First, as to the manner of holding the viscus, I soon found that traction loops passed through all the coats, as shown in Figure 2, held it just as well as clamps; second, if traction loops were placed on tension, thus lifting high a part of the front wall of the viscus (Fig. 3), the air in the viscus rose to the top so that when the lifted part was incised, the air escaped, the intravisceral pressure was destroyed, the fluid gravitated to the posterior and lower portions (Fig. 4) from which it could be dipped out with a ladle or dipper, and the viscus could be dried and made clean with gauze without spilling a drop of the fluid (Figs. 5 and 6); third, the hemorrhage could be controlled by temporary use of artery forceps or ligation of the vessels.

[2] Ann. Surg., December, 1910.

[3] Coffey, R. C., Surgical Treatment of Ulcers Along the Lesser Curvature, Surg., Gynec. and Obstet., December, 1910.

An exploratory incision in the stomach should usually be made transversely, thereby parallelling the vessels and avoiding hemorrhage almost entirely. Through such an incision, after the fluid has been removed by the technic just described, an accurate inspection of the stomach mucous membrane can be made with no danger of spilling the stomach contents or soiling the peritoneal cavity. If an ulcer exists, the remainder of the stomach may be explored for other possible ulcers and the general condition of the mucous membrane inspected. When an ulcer is found, as shown in Figure 4, it is then well to open the gastro-colic omentum and the gastro-hepatic omentum and pack the lesser peritoneal cavity with gauze, after which the ulcer may be excised by any technic which may be suitable for the case at hand, for, after the stomach is well cleaned and inspected as I have described, no matter where the ulcer is, it may be trimmed out with a pair of scissors exactly in the same way in which a bad spot in a garment may be trimmed out, preparatory to mending. The ulcer shown in Figure 4 for excision was located on the posterior wall near the attachment of the gastro-hepatic omentum. It was trimmed out by extending the exploratory incision down nearly to the ulcer, as shown by the dotted line, and then by the cutting out of the callous portion around the ulcer. The wound was then closed just as we would close the original exploratory incision, which process is as follows:

The line of sutures begins from within. The needle passes from within out and from without in and the suture is knotted inside as shown in Figure 7. The loose end is cut off and the suture continued by a right-angle, through-and-through suture the length of the incision. The traction loops are tied together over the line of union, as shown in Figures 8 and 9. These traction loops make inversion of the edges very simple. After this is done a peritoneal suture may be used to cover up all the knots (Fig. 10). This makes an ideal technic. In case the exploration reveals extensive ulceration at the pylorus or reveals a malignancy (Fig. 11) requiring a pylorectomy, the greater omentum below and and the lesser omentum above are ligated in sections and the vessels running along the curvatures of the stomach are doubly ligated at each end. The gauze is also packed into that part of the stomach which is to be retained as well as that part which is to be removed. The lesser peritoneal cavity having already been packed with gauze, the field of operation is practically extraperitoneal. The gauze within the ends of the stomach takes up every particle of the fluid. The exploratory incision is now extended to the point of cutting the stomach in two. Tenaculum forceps grasp the two walls of the stomach and the gauze in each of the divided ends. Two traction sutures are placed in the anterior and two in the posterior wall of the duodenum just below the place at which the section is to be made (Fig. 12).

The section of the duodenum is now made and the pylorectomy is completed. The distal cut end of the duodenum is held up by the four traction sutures, which arrangement causes the fluid to gravitate down the intestine while the end is being sutured after the manner shown in Figures 7 to 10. The cardiac pouch of the stomach is now inspected. If there is any portion of the remaining stomach which looks suspicious, it may be removed with perfect ease. If not, three additional traction loops are placed on the posterior wall of the stomach, as indicated, and the end closed in the manner shown in Figures 7 to 10. The cardiac pouch is now connected to the duodenum by a posterior gastro-enterostomy without clamps, as follows:

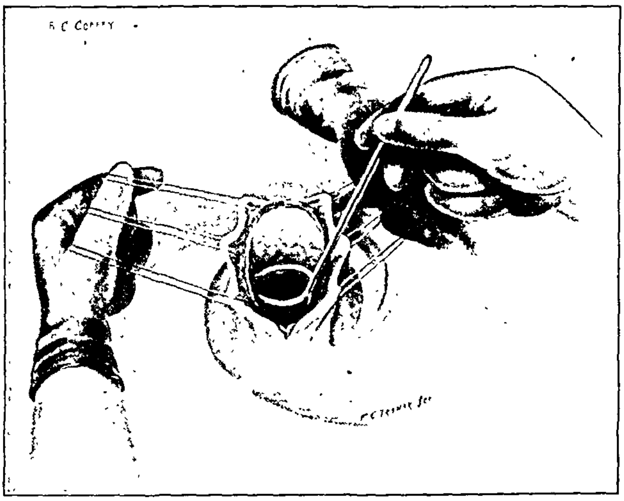

Fig. 5.—Dipping fluid from the open stomach with a ladle.

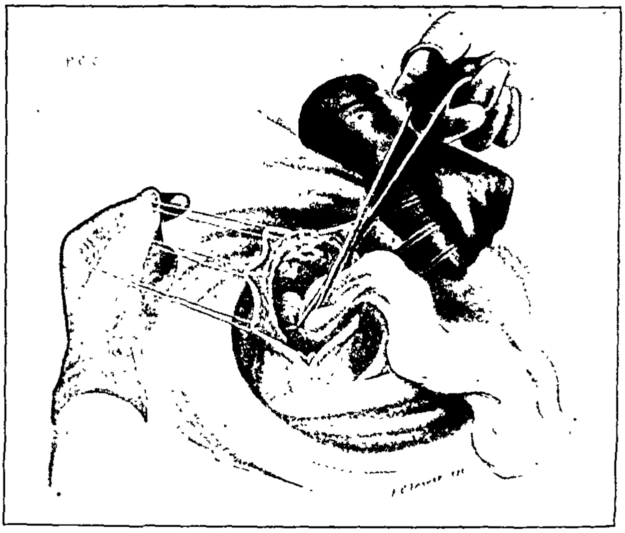

Fig. 6.—Sponging the mucous membrane dry with gauze.

An opening in the mesocolon is made with the finger or forceps just to the left of the ligament of Treitz. Four traction loops are passed through all the coats of the stomach and are so arranged that there will be one traction loop on either side of the end of the line of proposed incision, which line is about 2 inches in length. Four corresponding sutures are placed in the jejunum, the upper one being about 1 inch from where the jejunum emerges. The traction loops in the stomach nearest the intestine and the traction loops in the intestine nearest the stomach are designated inner traction loops (I. T. L.) as they are located inside the proposed line of incision into the stomach and intestine. The other traction loops are located outside the proposed line of incision and are designated outer traction loops (O. T. L.). Gauze sponges are now laid between the stomach and the intestine (Fig. 13). The next step in the operation consists in placing a continuous peritoneal suture (C. S. 1) as shown in Figure 14 which is begun at the end of the incision farthest from the operator. After two or three stitches have been taken the two inner traction sutures at this end are tied over the line of suture. The continuous peritoneal suture (C. S. 1) is then continued to the other end of the proposed incision just beyond the inner traction sutures. This continuous peritoneal suture (C. S. 1) is then knotted on itself and laid aside until all other steps of the operation are completed, when it is continued around the anastomosis as a finishing suture. The other inner traction loops are now tied together, and are from now on used to hold up the intestine (Fig. 15). In order to be sure that this peritoneal suture is not disarranged by the further steps of the operation, a continuous through-and-through suture of catgut is run from one pair of traction sutures to the other (on the posterior side only) before any incision is made in the stomach or intestine (Fig. 16). This suture has been designated the posterior reinforcement suture (P. R. S.).

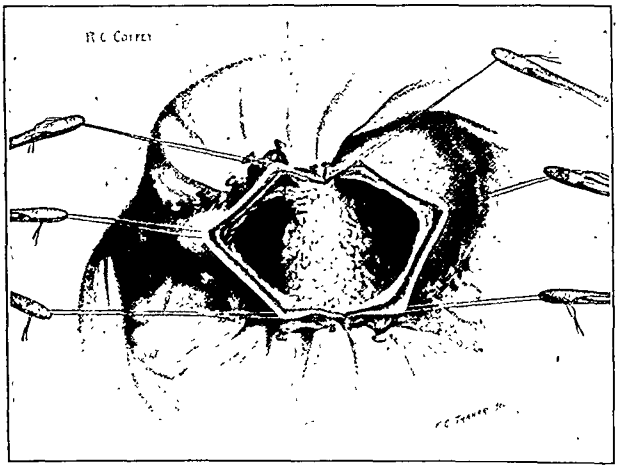

Fig. 11.—A transverse exploratory incision to determine the extent of a cancer of the pylorus developing on an ulcer. Gastrocolic and lesser omenta have been cut and the lesser puritoneal cavity is filled with gauze. The stomach has been emptied and dried, as in Figures 5 and 6. Vessels at the upper and lower borders of the stomach have been ligated preparatory to doing pylorectomy.

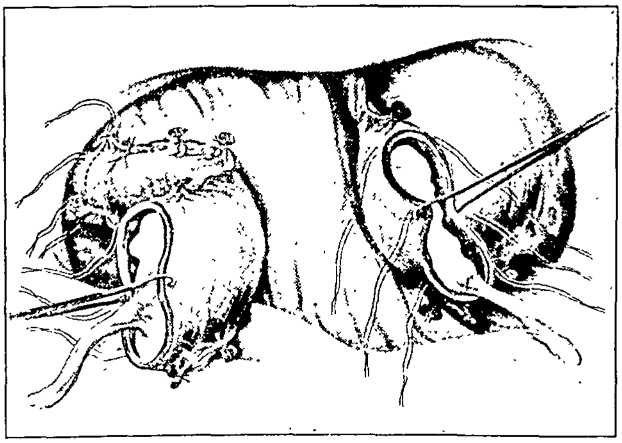

Fig. 12.—Stomach has been cut near the middle and each end is packed with gauze to prevent soiling. Three additional traction loops have been placed in back wall of the cardiac pouch preparatory to closing this remaining portion by technic, shown in Figures 7 to 10, inclusive. The pyloric portion has been freed and is ready to be removed by cutting the duodenum at the dotted line. Traction loops have been placed on each side of the duodenum to facilitate the technic of its closing.

An assistant now picks up the outer traction loops (O. T. L.) and lifts up the stomach and intestine while the surgeon makes an incision with the knife down to the mucosa and then opens the mucosa with a pair of scissors (Fig. 17). There will usually be two or three bleeding vessels on the stomach side which should be caught with mosquito forceps and ligated with small thread. It will be found on opening the stomach and intestine that the fluid has gravitated away from the field, leaving it perfectly clean and doing away with the necessity of any clamps or constriction. The second continuous suture (C. S. 2) then begins at the end of the anastomosis nearest the operator and proceeds as an over-and-over stitch to the opposite end (Fig. 18), when the corner is turned and this suture (C. S. 2) returns to the operator with a right-angle, continuous through-and-through suture indicated in Figure 19, where it is tied to its other end. The outer traction sutures are now tied over the line of union. The second continuous suture (C. S. 2) may be chromicized catgut or linen. For the final step of the operation the continuous peritoneal suture (C. S. 1) is now picked up and made to cover in the through-and-through suture and the knots of the traction loops, and it is finally tied to its originally free end (C. S. 1, Fig. 20) In more than fifty experimental operations by this method our average time has been about fifteen minutes. Under exactly the same circumstances we are able to do this operation just as quickly as when we have used the clamps. The line of suture is made much stronger at the ends by the inner traction sutures posteriorly and the outer traction sutures anteriorly than can possibly be done without the traction loops. The reader will readily observe the immense holding power of these traction loops after they are tied together, by looking at Figure 21, which represents a sectional view across the ends of the anastomosis. Figure 22 shows a sectional view across the middle of the anastomosis, which differs in results from the ordinary clamp method in use when clamps are employed only by having the posterior reinforcement suture.

We have recently removed the cecum for carcinoma and have then made an anastomosis between the ileum and the transverse colon by this method. To our delight we found that the fluid within the closed intestine, both large and small, had gravitated away from the field of operation, leaving the field perfectly clean (Fig. 23). The necessity for leaving an inch or two of dead end of the ileum and cecum into which part of the fluid at the site of operation may gravitate will readily be appreciated.

The gastro-enterostomy without clamps here described was primarily intended only for those cases in which the stomach had previously been emptied through an exploratory incision and it was thought that it would be necessary to constrict the intestine above and below with gauze to protect from intestinal contents, but we soon found that the field was much cleaner without constriction, for no matter how much we tried, the inclosed field could not be stripped perfectly clean when clamps were used. The gastro-enterostomy can be done without clamps on an unopened stomach provided the site of operation can be lifted to a higher level than the other portion of the stomach, and the fluid can be removed by the method shown in Figures 5 and 6. If, as a result of adhesions, or a short mesocolon, it is impossible thus to lift the stomach, it is necessary to empty it by the method shown in Figures 2 to 6, as a preliminary step, which process it is probably wise to follow in most cases of ulcer of the stomach for purposes of exploration. In simple uncomplicated obstructive ulcer at the pylorus not requiring exploration there is still a field for clamps.

CONCLUSIONS

In summing up I find:

First.—It is generally the opinion of progressive gastric surgeons that callous ulcers of the stomach not located near the pylorus should be excised, and there is a rapidly growing belief that the Rodman operation should be performed more frequently, (a) because the drainage operation does not always cure; (b) because of the large percentage of callous ulcers (26 per cent.) which become cancerous.

Second.—In order to do good ulcer surgery it is necessary to determine the extent and location of the ulceration. This can only be done properly as a rule through an incision in the stomach wall and when clamps are not used.

Third.—The incision should be ample and should usually be made transversely to avoid the vessels, after which step the inside of the stomach should be seen. By the use of deeply placed traction loops the anterior wall of the stomach is lifted, the gas in the stomach comes to the top and escapes when the incision is made, thus relieving the intragastric pressure. The fluid now immediately gravitates to the lower levels of the stomach cavity, from which it may be dipped and sponged with deliberation. After the stomach is thus emptied and the cavity dried, the inspection of the mucous membrane is easy and the mystery and difficulties of stomach surgery vanish; for the surgeon, after opening the omentum above and below the stomach and packing the lesser peritoneal cavity with gauze, proceeds to trim out the diseased portion with the same precision and completeness with which he would amputate a leg for gangrene or remove a breast for cancer.

Fourth.—By the use of traction loops, gastro-enterostomy may be done by the "no-clamp" method just as quickly as with the clamp method, much more directly and accurately, and with less soiling and less danger. Pylorectomy for ulcer or cancer is also done in a more correct surgical manner by using the traction loops than by the use of clamps. Another advantage is that the remaining portion of the stomach may be carefully inspected again after the gauze is removed from its cavity with the view of detecting any disease which may exist.

667 Glisan Street.

ABSTRACT OF DISCUSSION

Dr. J. W. Draper Maury, Rochester, Minn.: Many methods have been suggested for the excision of gastric ulcers and the last word remains to be said. This is because the problem is wrapt up in a cancer equation yet to be solved. Sufficient is known, however, to justify the positive statement that any technic which does not insure the freest possible removal beyond the ulcer margin is worthless, because in over 70 per cent. of ulcers the margin is carcinomatous. At St. Mary's hospital we have worked out on animals a method of ulcer excision by a strangulation stitch which under certain conditions has certain advantages over ordinary excision. In the majority of cases it cannot be used to advantage. It is much more rapid than excision; has been free from fatality in experimental work and does away with all hemorrhage and annoying gaping of the wound. It seems to me probable, however, that even the limited use to which we thought it might occasionally be put will probably be still further restricted by the method that Dr. Coffey has just presented.

A stitch consisting of two pentagons, one lying on the mucous surface of the stomach, the other on the serous surface, may easily be applied by a continuous suture. The tissue within the pentagons will be deprived of blood-supply when inversion and tight tying of the stitch occurs. It is obvious that an odd-sided figure must be used in order completely to surround and "scissor" the included tissue. Dr. Selby, by the clever employment of litharge and wire, has prepared a radiograph of a hypothetical ulcer. In this, double strands of the stitch can readily be seen and its constricting action understood.

In from fifty to one hundred hours the gangrenous tissue, including the ulcer, sloughs. Dr. MacCarty has made some studies on the residual tissue which suggest encouraging results.

The essentials in the use of this method are as follows: (1) The use of heavy linen twine which the bare hand cannot break; (2) the placing of the pentagon well beyond the ulcer in normal tissue; (3) the careful suturing of the serosa by Lembert stitches after the pentagon is tied. Without these it will certainly perforate.

Dr. W. W. Skinner, Geneva, N. Y.: Possibly some present heard me describe very briefly at Atlantic City two years ago the operation which has been described so ably to-day. Dr. Zimmer of Rochester, N. Y., and I made use of this method in 1896. The case was one of bullet wound perforating both walls of the stomach. At my suggestion the bullet wound in the anterior wall of the stomach was enlarged and the stomach contents, which consisted of a large supper eaten just before the accident, were removed. The posterior wall of the stomach was pulled through the anterior stomach incision, the bruised posterior area cut out, and the incision enlarged sufficiently to inspect the region behind the stomach, so that we were able to trace the bullet wound through the tail of the pancreas and into the muscular tissues behind. This patient made an admirable recovery. The posterior cut was sewed from the inside of the stomach with three layers of stitches. We used the buttonhole stitch. Since then I have used this operation a number of times in cases of posterior ulcer of the stomach, which I referred to in the discussion two years ago.

The advantages of this operation are very great. In the first place, if you make a vertical incision through the lesser omentum, the exposure of the posterior wall of the stomach is very inadequate; if you make an incision transversely to the line of the body, you cut off important blood and lymphatic supply and nerves. An incision through the anterior wall of the stomach, selecting a place where the blood-vessels are very few, is comparatively free from danger.

A method which I use in some cases is the following: During the first stages of anesthesia a small-sized nasal feeding tube is passed through the nose into the stomach; the stomach is washed out while the anesthesia is going on and the tube is left *in situ;* and then just before opening the stomach this washing is repeated.

During the anesthesia there will be jets of green fluid from the tube, which otherwise would be spilled into the peritoneal cavity. This procedure causes no strangling and no trouble.

I agree with Dr. Coffey that no clamps are needed. It is sufficient to pull the posterior wall of the stomach through the anterior. That makes a sufficient clamp, and the preliminary washing prevents infection.

When I use clamps, I am accustomed to make use of very small and simple ones. I refer to the ordinary little pine tongue-depressors that are sold by the thousand. They make a most admirable clamp, if thoroughly steamed, boiled or otherwise sterilized. The trouble with the steel clamp is that it exerts a constant and increasing pressure, whereas the little pine pieces (of which I use four tied with catgut) exert a uniform flat pressure throughout the operation.

DR. E. WYLLYS ANDREWS, Chicago: If we are about to return to the direct surgical treatment of gastric ulcer, which was so nearly supplanted in routine practice by the general adoption of gastro-enterostomy, it would be well for us to remember certain advantages and certain disadvantages of this direct method of operating. As to the advantages, those who have not tried direct opening of the stomach are not aware of the great ease and safety with which that organ can be laid widely open and its whole interior exposed. No clamps are necessary, the field can be amply protected by sponges, and the stomach can be drawn entirely out and lie on the anterior abdominal wall. The incision can be made vertically between two of the large superficial branches of the vessels running on the greater curvature, and made bloodless and as long as we wish it; that is, the length of the incision may be made the whole width of the stomach. With such an opening one can explore nearly the whole interior of the stomach and can close it again quickly and safely.

Long-continued experimentation on animals, as well as many successive operations on the human stomach, have led me to lose all fear of this procedure as one step in necessary technic.

If the pendulum is going to swing in the direction of this kind of work again, one must mention among the disadvantages that certain parts of the stomach cannot easily be inspected. At least 6 per cent. of the peptic ulcers lie near the cardia and that portion of the stomach cannot be drawn out or seen except by means of a glow lamp or reflected light. Ulcers near the pylorus cannot be drawn out or treated surgically, unless by a Rodman excision, or as Kocher and some others did, by pyloroplasty directly through the pylorus. In bleeding ulcer, or a peptic ulcer not bleeding, one perhaps causing obstruction, Finney's operation is more radical and effective than pyloroplasty. A further problem and drawback to this kind of work is the puzzle of what to do after finding the ulcer. The ulcer may be excised and the wound sutured; the vessel if bleeding may be ligated inside or outside the stomach wall, or at the bottom of the ulcer; the ulcer may be treated by the hot cautery point and some bleeding vessels thus checked; or the ulcer may be ligated by lifting a cone of stomach tissue from the inner aspect. But this is somewhat unsatisfactory and dangerous, unless protected by an outside row of stitches. After having solved the problem of opening and finding the ulcer, which of itself is not always easy, with all the proposed and tried methods of dealing directly with ulcer, none of them as yet has seemed to be ideal.

DR. CHARLES H. MAYO, Rochester, Minn.: In something over 1,100 gastro-enterostomies performed at our clinic, we have encountered about every kind of complication. We have had nothing serious in the line of operative injury that Dr. Coffey speaks of, and yet we have had to reopen wounds on account of hemorrhage in the line of union, or the suture line, from the stomach to the intestine. We have also had to reopen because of hemorrhage from the ulcer, and we have had deaths occur following hemorrhage from the ulcer, and from perforation, although in the old days we were taught to believe that ulcer was cured and all hemorrhage would cease the moment gastro-enterostomy was performed. But we all know that gastro-enterostomy is merely a drainage operation and does not have a healing action on the ulcer. With drainage unobstructed, the ulcer may get well, but merely because a patient stops bleeding from an ulcer, or the pain ceases, is no sign that the ulcer has healed.

An excavating ulcer does not become cured unless excised or unless Nature cures it by a perforation. When Nature perforates an ulcer, all the coats are brought together and up to that point it is not a recurring ulcer but the same ulcer. The point is merely that it dips in a little deeper or spreads wider. Maury has devised a stitch which can be used on deep ulcers and to control hemorrhage, which has been used experimentally on animals, and we have used it on the human subject in a few instances, apparently with great benefit.

The question of whether or not we should use clamps is a point of technic. We much prefer to use steel clamps occasionally. One cannot otherwise always get a stomach up as it is necessary to do to carry out the technic presented by Dr. Coffey in his excellent paper.

In the treatment of ulcers we should recognize and overcome the danger of hemorrhage and recognize the possibility of the subsequent development of cancer, since ulcers of the stomach are liable to precede carcinomatous conditions.

Ulcers in the duodenum, embracing nearly two-thirds of all the ulcers in this region, are fortunately not prone to become carcinomatous. Very few operators, in a lifetime of surgery, will ever see a primary cancer of the duodenum, except at the ampulla, where the intestine is opened in excising the carcinoma; but it really does not belong primarily to the duodenum; therefore circular sutures may be used on an ulcer in that location to depress it, if the tissue resistance is such that it can be depressed, and protecting sutures can be placed over the point of inversion.

This operation is a serious one if there is but little acid in the stomach. Often the stomach acid content is very low, and patients succumb to sepsis.

DR. A. J. OCHSNER, Chicago: Severe, dangerous hemorrhage has occurred so seldom after the application of ordinary pressure clamps in the operation of gastro-enterostomy that I believe when it does occur it is because of the softened condition of the tissues in the vicinity of the ulcer. If the clamp is applied within a relatively short distance from the ulcer, I believe that the accident which happened in this case is not only possible but likely to occur. Ordinarily that is not necessary. The anastomosis should always be made at the lowest point of the stomach, as shown us many years ago by W. J. Mayo; and when that is done, I believe that one can safely apply the pressure-clamp without the danger of hemorrhage. I have seen two or three cases of hemorrhage in instances in which the sutures were not as perfectly applied as they should have been, at the junction of the gastro-epiploic vessels with the wound. But the danger of which Dr. Coffey speaks I believe is one which occurs only rarely and which should be avoided. In cases in which one cannot make the anastomosis at a considerable distance from the ulcer, one should perform the operation which Dr. Coffey has shown us. All of the facts which Dr. Coffey has illustrated here I have personally experienced. The fear of soiling and of hemorrhage during the operation really amount to very little, if the operation is performed as described by Dr. Coffey.

Many years ago, while I was Professor Senn's assistant, he made this identical operation. Since that time I have performed this operation by applying very delicately toothed forceps to the blood-vessels at the margin, grasping all of the layers of the intestinal wall, that is, the mucous layer, the muscular layer and the serous layer, and placing these clamps at regular intervals.

As regards the pentagonal stitch that Dr. Maury has shown us, the difficulty about that stitch in practical application is this: It works beautifully in the stomach of the dog, and undoubtedly would work beautifully in the normal human stomach. Since Dr. Maury has introduced this stitch I have not had a case in the human being in which it seemed as though it would work. Where the ulcer is small it is not necessary, and where the ulcer is large you would have to fold in so large a portion of the stomach wall that the covering would be very much more difficult and much more prone to cause a troublesome deformity which might ultimately result in obstruction, than would simply excising the ulcer and making the suture as done in Dr. Coffey's cases.

Regarding the operation that Dr. Skinner has described, I wish to state that in 1891 Dr. Charles T. Parks described this very operation and performed it in a case of gunshot wound through both the anterior and posterior walls of the stomach.

Speaking of approaching the posterior wall of the stomach, the best way, if the anterior wall is punctured by a small perforation, which is very commonly the case in gunshot wounds, is to lift up the transverse colon and split the transverse mesocolon precisely as one does in posterior gastro-enterostomy, which is a much more simple operation than the one that has been described. Then drain through the lesser omentum, and you still have perfect drainage.

Dr. Robert T. Coffey, Portland, Ore.: The technic of sewing is the same as that used when we use clamps. The principle that I wished to bring out was the method of lifting up the front wall of the stomach with traction loops, thereby making an air bubble which escapes when the stomach wall is incised and relieves intragastric tension; the fluid then gravitates to the lower levels and may be dipped or sponged out without spilling, and much more perfectly than when clamps are used or by the freehand methods which previously have been described. Danger from the spilling of fluid contents is not great, but it is annoying to an esthetic operator, and it can be avoided providing you lift the parts up as shown. That is the principal point. As to describing the technic of removing the ulcer, that is not intended to be a major part of the paper at all. It is simply a matter of so cleansing the stomach that we can go ahead and do any operation which seems advisable on the stomach with just as much ease and care and just as much nicety as we can amputate a leg. Besides using the traction loops for holding the stomach while cleansing, I have used them to strengthen greatly the line of suture and facilitate the turning of peritoneal surfaces.

Dr. Andrews stated that it was impossible to see ulcers of the cardia. It is not impossible, if you will make an incision at right angles to the median incision following the rib arch on the left side. You will find that you can very easily inspect the entire stomach from the inside, and I have done so in two cases in which the ulcer was located very close to the esophagus. It also is possible to inspect the pyloric section after the stomach is wide open. I hoped to learn from the discussion how frequently hemorrhage resulting from pressure of clamps had occurred, and I am surprised but glad to learn that it does not occur in the experience of anyone else. In the case described the vessel was open where it crossed the slit which had been made by the clamp; furthermore, there had been no hemorrhage either from the original ulcer or the site of operation. The anastomosis was made at the lowest point of the stomach and was more than 4 inches from the ulcer, thus avoiding the criticism of Dr. Oschner. The fact remains, however, that if anyone desires to investigate the result of clamps on the mucous membrane he will be surprised to note that it is broken or slit in a very large percentage of cases. It would be surprising if there have not been more serious hemorrhages resulting from clamp pressure than is indicated by the discussion to-day. I have done many hundreds of experimental anastomoses in addition to my clinical work. Most of my experimental anastomoses have been done by the various free-hand and traction-loop methods with a view to learning to sew skilfully, but, like Dr. Mayo, I have not heretofore done any clinical work without clamps. By the technic here described, however, I have been able to do even more satisfactory work in excisions of ulcers and in doing pylorectomy for carcinoma than I have been able to do with the clamps, leaving out the possible danger from clamp pressure. It is unquestionably cleaner, more thorough and more surgical. The gastro-enterostomy described is, as will be noted, a sequel or part of the gastrectomy and is used after the stomach has been emptied of its contents. The traction loops when tied unquestionably add material strength to the union. I am not prepared to advise the discarding of clamps in cases of simple gastro-enterostomy for simple unquestionable pyloric or duodenal obstructive ulcers when there is no call for exploration. This, however, is the only field, it seems to me, in which clamps can be used to advantage.

SMOOTH ATROPHY OF THE TONGUE *

LINDSAY S. MILNE, M.D.
NEW YORK

For many years the occurrence of smooth atrophy of the base of the tongue in cases of syphilis was handed down as a tradition in Virchow's laboratory in Berlin and from this source chiefly the first knowledge of the condition was disseminated.

Since the publication of Lewin and Heller,[1] however, in 1894, comparatively little has been written about smooth atrophy of the base of the tongue in reference to its diagnostic value in syphilis. In their series of 6,583 cases which came to autopsy in the Charité Hospital in Berlin, 200 presented a history of syphilis, 156 acquired and forty-four congenital. Of these, eighty-five cases of acquired syphilis showed no smooth atrophy. One hundred and three cases presented smooth atrophy of the base of the tongue and of these, seventy-one (69 per cent.) have a definite syphilitic history. Thus, in 45 per cent. of cases of acquired syphilis smooth atrophy was found to occur.

Symmers (1910),[2] in 623 cases, found seventy-five in which there had been a distinct history of syphilis, and in sixty-four (84 per cent.) of these, smooth atrophy of the base of the tongue was noted, fifty-five complete and nine partial. In three of his syphilitic cases the lymphoid follicles at the base of the tongue were hyperplastic.

In this institute, smooth atrophy of the base of the tongue has been looked for as a routine and its occurrence noted fairly frequently. In 1909, out of 505 autopsies, it was found in thirty-nine cases (twenty-five male and fourteen female). In all of these the condition was quite definite, all doubtful cases in which atrophy was only slight or moderate being excluded. In three, however, it was only partial, but in the affected portions was quite distinctive.

The accompanying tables indicate the class of case in which this condition of smooth atrophy was found, and its relationship to syphilis.

TABLE 1.—SMOOTH ATROPHY OF THE BASE OF THE TONGUE, BUT NO HISTORY OR SIGNS OF SYPHILIS AND WITH A GOOD FAMILY RECORD

Case.	Sex.	Age.	Cause of Death.
1	M.	66	Acute yellow atrophy of the liver.
2	M.	65	Cancer of rectum.
3	M.	29	Phthisis.
4	M.	60	Pneumonia, pericarditis, advanced general arteriosclerosis.
5	M.	51	Phthisis and acute suppurative peritonitis.
6	M.	74	Pneumonia.
7	M.	50	Cirrhosis of the liver with primary cancer.
8	M.	59	Cerebral softening and senile atrophy.
9	F.	62	Gangrene of lung following operation on hemorrhoids.
10	F.	28	Disseminated sclerosis.
11	F.	54	Senile atrophy general.
12	F.	65	Nephritis.
13	F.	40	Carcinoma of uterus.
14	F.	62	Pemphigus.

TABLE 2.—SMOOTH ATROPHY OF THE BASE OF THE TONGUE WITH NO SIGNS OF SYPHILIS. HISTORY OF SYPHILIS DENIED, BUT POSSIBLY MAY HAVE OCCURRED

Case.	Sex.	Age.	Cause of Death.
1	M.	47	Pneumococcal pericarditis (gonorrhea several times).
2	M.	55	Cirrhosis of the liver (chronic laryngitis, not tuberculous, possibly syphilitic).
3	F.	77	Cancer of the cecum (5 children, all died young; had 1 miscarriage).

---

TABLE 3.—SMOOTH ATROPHY OF THE BASE OF THE TONGUE NO SIGNS OF SYPHILIS. HISTORY OF SYPHILIS NOT KNOWN

Case.	Sex.	Age.	Cause of Death.
1	M.	77	Senile atrophy and general arteriosclerosis.
2	M.	60	Senile atrophy and general arteriosclerosis with terminal acute cystitis.
3	M.	78	Nephritis.
4	M.	47	Appendicitis (also had mitral stenosis).
5	M.	63	Phthisis, intestinal tuberculosis (no laryngitis).
6	M.	64	Phthisis; intestinal tuberculosis, chronic tuberculous laryngitis; tabes mesenterica.
7	M.	80	Infarction of heart; general arteriosclerosis.
8	F.	65	Tuberculous peritonitis and acute miliary tuberculosis (few small ulcers in the upper part of esophagus, but no laryngitis).

TABLE 4.—SMOOTH ATROPHY OF THE BASE OF THE TONGUE WITH A DEFINITE HISTORY AND SIGNS OF SYPHILIS

Case.	Sex.	Age.	Pathology.
1	M.	36	Sacculated aneurysm, arch of the aorta (rupture into right pleura).
2	M.	40	Syphilitic ulcer of face (death from general septicemia).
3	M.	65	Syphilitic scarring of liver (death from empyema).
4	M.	60	Syphilitic scarring of liver and skin (death from nephritis).
5	M.	43	Tabes dorsalis.
6	M.	63	Tabes dorsalis.
7	M.	58	Tabes dorsalis; also syphilitic scarring of the liver.
8	M.	45	General paresis.
9	F.	27	Syphilitic ulcer of perineum, chronic syphilitic laryngitis and pharyngitis; also scars in liver (died of purulent cystitis and pyonephrosis).
10	F.	46	Old syphilitic skin lesions (nephritis case).
11	F.	53	Old syphilitic skin lesions (cerebral softening, nephritis case).
12	F.	36	Syphilitic scarring of the liver and skin (death from nephritis).
13	F.	54	Saber tibiæ and syphilitic scarring of the liver (gumma of brain).
14	F.	45	Syphilitic ulceration of the nasal cartilages, syphilitic laryngitis (death from liver cirrhosis).

TABLE 5.—CASES PRESENTING MANIFESTATIONS OF SYPHILIS, BUT NO SMOOTH ATROPHY OF THE BASE OF THE TONGUE

1. Old syphilitic skin lesions:

Case.	Sex.	Age.	Cause of Death.
1	M.	40	Acute endocarditis.
2	M.	59	Cerebral thrombosis and softening.
3	M.	49	Chronic cardiac dilatation and chronic arthritis.
4	M.	65	Pneumonia and pericarditis.
5	F.	53	Cerebral thrombosis and softening and nephritis.
6	F.	92	Pneumonia.

2. (a) Aneurysm of aorta—sacculated.

1	M.	53	Cardiac failure.
2	M.	59	Rupture into pericardium.
3	M.	45	Rupture into superior vena cava.
4	F.	57	Abdominal, dissecting, rupture into right pleura.

(b) Aneurysm of aortic arch fusiform. Three cases (no aortic incompetence): One denied syphilis but presented numerous syphilitic scars on the legs and abdomen. The other two admitted syphilis but showed no other signs than very extensive arteriosclerosis.

3. Tabes dorsalis and old syphilitic skin lesions:

1	M.	59	
2	M.	42	Tabes dorsalis.
3	F.	44	Tabes dorsalis; syphilitic scarring of the liver; syphilitic pulmonary fibrosis.

4. Syphilitic pulmonary fibrosis:

1	M.	77

5. Syphilitic scars in the liver (pneumonia case):

1	F.	56

6. Syphilitic scars in liver and skin, syphilitic laryngitis and ulceration of the pharynx with disappearance of the uvula (died of liver cirrhosis):

1	F.	47

7. Saber tibiæ—(old chronic cardiac dilatation case):

1	M.	60

8. Syphilitic aortitis, rupture of aortic cusps:

1	M.	37

Total.. 21

As a summary of these thirty-nine cases it may be seen that they occurred at all ages between 27 and 80. Age alone does not produce this condition, as subjects of 90 years or over do not show it. In fourteen there was typical smooth atrophy with a negative history and no signs of syphilis. In fourteen it existed in cases presenting definite evidences of syphilis. In twenty-one syphilitic cases, however, there was no apparent abnormality of the base of the tongue. These numbers are of course too small to form any statistics, yet they correspond practically to the experience of past years in this laboratory.

In cases of active syphilis there seems commonly to be a hyperplasia of the lymphoid tissue at the base of the tongue, as in the following three cases:

CASE 1.—Male, aged 42; syphilis at age of 25; syphilitic ulcers of the skin and scars in the liver, and syphilitic ulcer of the aortic arch which had eroded into the trachea and through which a fatal hemorrhage had occurred. The heart weighed 300 gm.; spleen 150 gm.; no chronic nephritis; slight general lymphatic glandular enlargement had occurred. The lymphoid tissue at the base of the tongue was considerably hyperplastic.

CASE 2.—Male, aged 27; syphilis eighteen months previous to date of death. Patient died very suddenly, apparently from asphyxia; larynx almost completely stenosed by syphilitic granulations; epiglottis and uvula destroyed by ulceration; extensive chronic skin lesions of syphilis and several gummata in the liver; syphilitic aortitis; heart weighed 250 gm.; spleen 215 gm.; no chronic nephritis. There was slight general lymphatic gland enlargement and considerable hyperplasia of the lymphoid tissue at the base of the tongue.

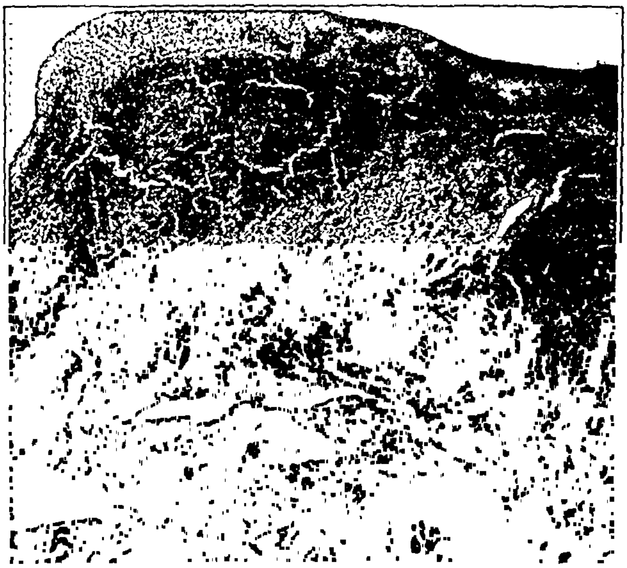

Fig. 1.—Section of the base of the tongue, showing extensive lymphoid hyperplasia of the lymph structures under the epithelium.

CASE 3.—Male, aged 39; syphilis twelve months previous to date of death. Patient died of chronic cardiac dilatation. He had also for several months previous to death a swinging temperature. There were some syphilitic scars on the legs and a persistent sore on the side of the tongue. His blood gave a positive Wassermann reaction before antisyphilitic treatment was commenced. His kidneys showed a marked chronic nephritis and the heart was enormously hypertrophied and dilated (770 gm.). The spleen was somewhat enlarged (525 gm.) and the lymphatic glands all through the body were very considerably swollen. The histologic picture of the blood showed no important change. The lymphoid tissue at the base of the tongue was very markedly hyperplastic, both grossly and microscopically.

In only one of the thirty-nine cases did the appearance warrant an absolutely certain diagnosis of syphilis. In this there was a specially indurative cicatricial character to the lesion and it was associated with a syphilitic laryngitis. All the other cases simply presented a smooth atrophic appearance of the surface structures of the tongue with disappearance of the papillæ. On microscopic examination the condition seemed to be an atrophy of the lymphoid and other subepithelial elements, so that a thin layer of squamous epithelium extended over an underlying fibrovascular structure, which, unlike the normal surface structures of the base of the tongue, contained no glands or lymphoid follicles.

There seemed to be no cicatrizing process and the subjacent muscle structures were undisturbed. In none was there any perivascular lymphocytosis, endarteritis, or other suggestively syphilitic process to be observed. In the relatively early stages of tertiary syphilis, as already noted, it is common to find a marked general glandular enlargement with also a hyperplastic condition of the lymphoid elements at the base of the tongue. Is this, then, a stage in the process whose final condition is smooth atrophy? No definite transition types were observed, but very probably it may be so, just as the lymph-follicles in the intestine may atrophy after typhoid fever.

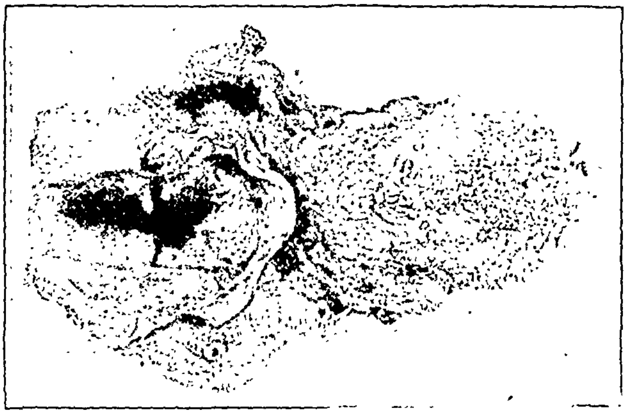

Fig. 2.—Smooth atrophy of the base of the tongue.

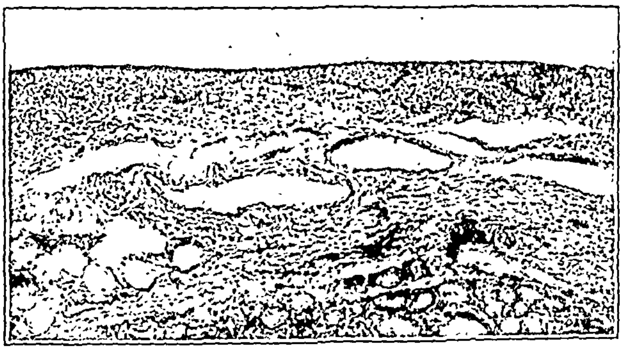

Fig. 3.—Section of the base of the tongue showing atrophy. The lymphoid tissue has entirely disappeared. (This section was taken from a position similar to Figure 1.)

In conclusion, then, these cases would seem to show that smooth atrophy of the base of the tongue may occur occasionally in other conditions besides syphilis, as, for instance, in certain tuberculous cases and in association with general wasting states. In tuberculosis, for instance, out of twenty-five cases of smooth atrophy of the base of the tongue in which syphilis could not be definitely determined, seven were tuberculous. Only these seven, however, out of 196 tuberculous cases in the same series of 505 autopsies showed the condition.

Of all the disease processes which lead up to the production of smooth atrophy of the base of the tongue syphilis is much the most frequent. In such proportions as in the present series, in which it existed in fourteen out of thirty-six syphilitic cases, the association is significant and at least a guide in clinical diagnosis.

Sixty-Sixth Street and East River.

A CASE OF BRAIN TUMOR

O. T. MANLEY, M.D.
CLEVELAND, OHIO

Patient.—The patient, Leonard H., aged 19, was referred by Dr. R. M. Manley, who made the ocular examination given later in this paper.

History.—The family history was negative. As a nursing baby, he had two convulsions, finished sixth grade in school with good grades, passing regularly. When 14, he was pushed from a moving street car, striking on head, was unconscious 30 minutes; vomited and developed conjunctivitis of right eye, which subsided in two weeks. His health was good for one year, at the end of which time convulsions occurred, and recurred for three years at intervals of from two to four months. During the year following the last convulsion, which occurred April, 1910, his headaches had gradually increased in severity, were almost continuous, and were accompanied by impairment of vision when I first saw him, April 1, 1911. Syphilis was denied. Potassium iodid had been administered but was not tolerated.

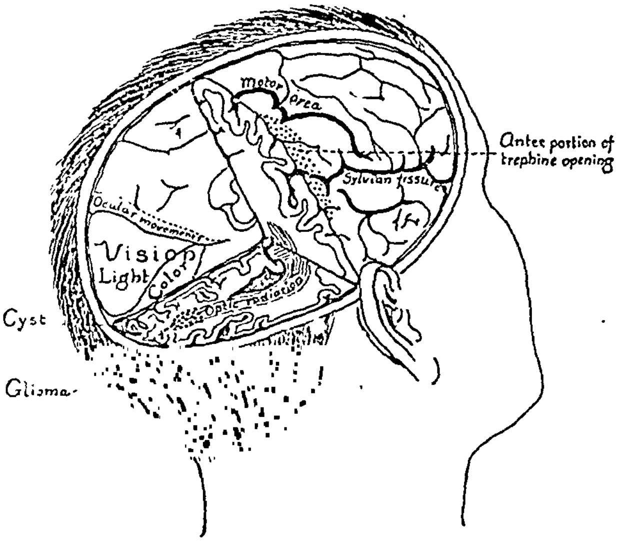

Fig. 1.—Perpendicular and horizontal dissection of right cerebral hemisphere, also showing mesal surface of posterior portion of left hemisphere.

Symptoms.—Headaches, tender area about 3 cm. diameter, on right side of scalp, 5 cm. perpendicular from the median line toward external auditory meatus, and a less tender area 4 cm. posterior to a corresponding point on the opposite side, muscular power of left hand diminished. Homonymous hemianopia (right halves of both retinæ blind). Unilateral hemichromatopsia (temporal half of left retina color blind) with variable vision for color and natural objects, and diminished acuity for light. Left pupil slightly larger than right. Pupillary reaction to light diminished on blind side with left pupil less active than right. He carried his head rotated to the left or his eyes to the left. Double choked disks and hemorrhagic retinitis. R. B. C. 4,900,000, W. B. C. 18,000, hemaglobin 90 per cent. Pulse 104, temperature and respiration normal. Motor, sensory, deep reflexes, coordination and urinary examination and other physical examination negative.

Diagnosis.—1. Increased intracranial pressure. 2. Central lesion, involving right optic radiation or visual center, probably extending toward thalmus, and possibly originating in parietal lobe toward the tender area on the right side.

Prognosis.—Unless the course was interrupted, prognosis was continuous and increasing headaches with total loss of vision and mental activity resulting in death.

Operation.—To relieve the pressure by a decompression trephining or to discover that its cause might permit of a successful removal, I opened the cranial cavity by a two stage osteoplastic flap operation, including the tender area on the right side in the upper anterior angle. At St. Alexis Hospital, April 3, I resected the bone and replaced the flap; April 10 I turned back the flap and opened the dura which was bulging, with no pulsation. The brain presented through the incision and required pressure to prevent its escape, as the dural opening was enlarged. There were irregular areas of dusky red and darker areas apparently degenerative covering the lower two-thirds of the exposed surface and infiltrating into the normal brain tissue toward the median line. The bone was removed and the opening in the skull enlarged downward and backward to allow protrusion of the brain without injury, and closure of the skin flap with less pressure. A needle was carefully introduced toward the posterior horn of the lateral ventricle to a depth of 3.5 cm. but no fluid was found. A section was removed for microscopic examination and scalp incision closed. Dr. Schumacher reported this section to consist of normal brain tissue with areas of pressure necrosis.

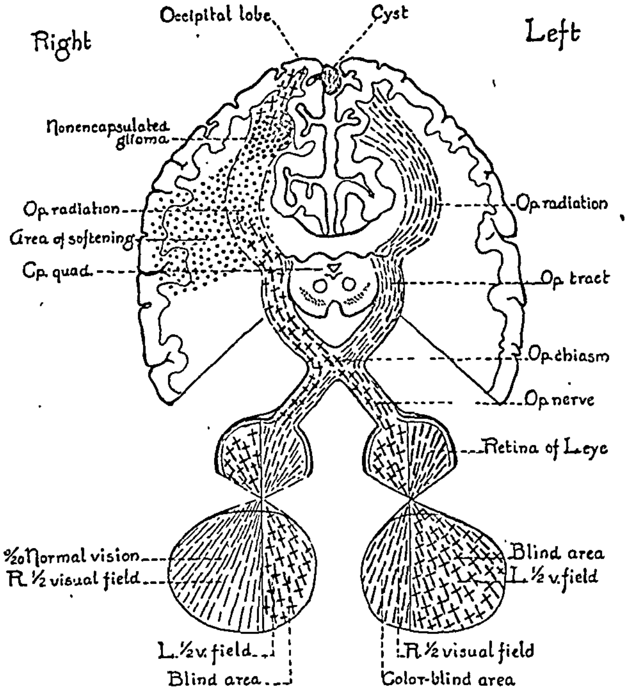

Fig. 2.—Horizontal cross-section of cerebral hemispheres.

Postoperative Condition.—First twenty-four hours: General condition good, conscious in thirty minutes, no shock, paralysis, headache or vomiting.

Second day: Partial paralysis of left hand and wrist, nystagmus (eyes rotate to left slowly and jerk to right). Pupillary reaction to light improved in both eyes.

Third day: Vision in the right half visual fields improved. General condition improved, excepting paralysis of left hand, which was more pronounced. No nystagmus.

Fourth day: General condition improved, walked to chair with assistance, slight discharge of cerebrospinal fluid.

Fifth day: Free discharge of cerebrospinal fluid.

Sixth day: Removed from hospital to home; condition good; no vomiting or headaches.

Second and third weeks: Free discharge of fluid but gradual enlargement of cerebral hernia, with progressive paralysis of left leg. No change of vision; was in chair; appetite good; temperature had been practically normal, pulse ranging from 72 to 90 and respiration 18 to 20, since the operation and continued so until the evening of the 17th day, or April 26, when vomiting occurred and pulse became rapid (120). Both subsided the next day but recurred April 29, after which time the discharging fluid was bloody. Death occurred May 2 in coma.

Ocular Examinations by Dr. R. M. Manley.—March 16, 1911, complains of poor vision, diplopia, and pain in the head. Lids and conjunctivæ normal; tension normal; no pain. Right pupil reacts to light and accommodation; left reacts feebly if at all. Left pupil contracts when cone to light is thrown into right eye; media clear; optic neuritis both sides with hemorrhages into retinæ; veins dark and enlarged both sides; right eye vision equals three-sixths, left eye vision equals two-sixths; esophoria varying from 12 degrees to 20 degrees.

March 30, 1911, homonymous hemianopia; right eye vision equals two-sixths, left eye vision equals one-sixth; both optic neuritis and hemorrhage increasing; urinary examination negative.

April 24, 1911, postoperative examination shows optic neuritis diminished; hemianopia remaining; right retina pale, veins small, very little hemorrhage remaining; left retina veins dark and larger than right, some hemorrhage; right, vision much improved; left, vision very much improved.

Fig. 3

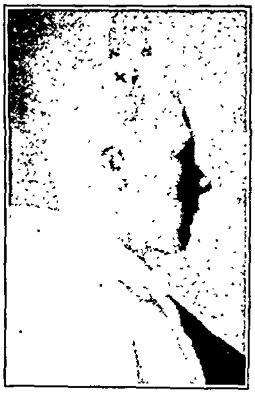

Fig. 4

Fig. 3.—Patient with brain tumor from photograph taken April 21, 1911.

Fig. 4.—Photograph in which x indicates tender area. Taken April 21, 1911, before operation.

Autopsy.—Autopsy was permitted only through the trephine opening which was 6½ by 8 cm. All the parietal portion beneath and posterior to the opening was softened and degenerated to a pulpy consistency, and offered little resistance to pressure. This was carefully removed and consisted of particles of apparently degenerated brain tissue mixed with bloody débris. A firm substance about the size of a goose egg was palpated in the posterior portion of the right side of the cranial cavity which was partly adherent to the falx cerebri; on removal, this proved to be the right occipital lobe with a cyst attached to the posterior portion of the calcarine fissure. The center and the anterior portion consisted of a non-encapsulated cheesy-looking substance which filled the space belonging to the optic radiation fibers; this was quite firm and in it could be detected small hard particles feeling like small spicules or minute calcified areas. On microscopic examination, this mass proved to be a glioma.

Pathologic Examination by Dr. Josephine Danforth.—Diagnosis: Infiltrating glioma of brain with calcareous deposits and cystic and degenerative changes.

Macroscopic: Specimen received for examination consists of:

1. A portion of the occipital lobe of the cerebrum which contains on its dissected surface an infiltrating growth about the size of a walnut with a cyst of the arachnoid on the external surface which corresponds to the mesal surface of the occipital lobe. This growth is soft in consistency, central portion disintegrating, greyish in color, and contains a few small spicules of bony substance.

2. A considerable amount of soft degenerated tissues.

3. Two small pieces of brain tissue removed with the degenerated tissue.

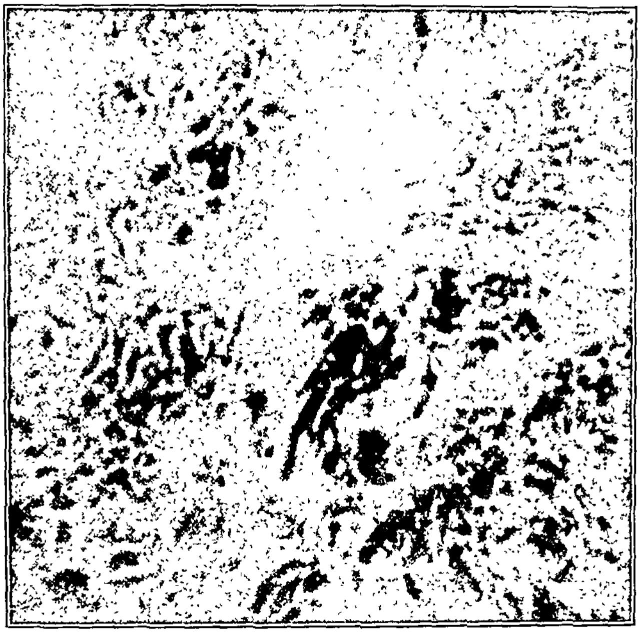

Fig. 5.—Glia cells.

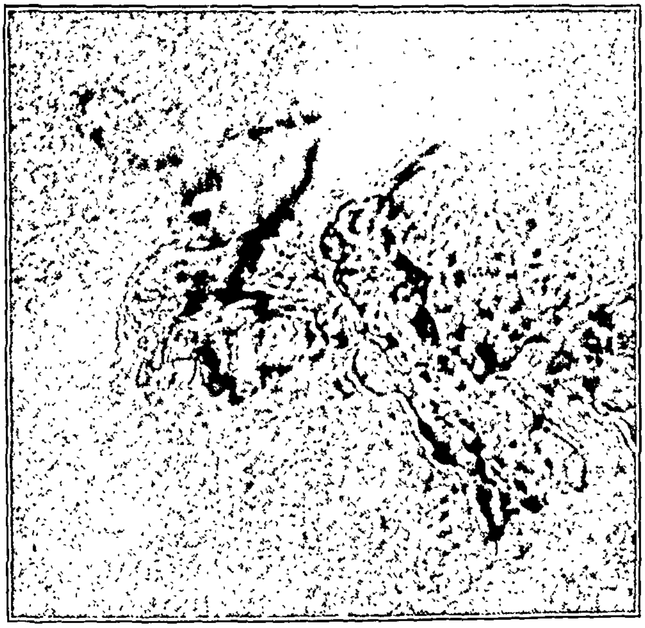

Fig. 6.—Calcareous concretions.

Microscopic: 1. (*a*) Tumor: Slides show masses of small cells having a distinct round or oval nucleus which fills most of the cell body. Many of these cells show distinct processes *drawn out in fibrils* which, interlacing, form a felt-like stroma. These are the glia cells (Fig. 5). Other portions of the slides show:

I. Areas of marked degeneration of all cellular structures, infiltrated with polynuclear leukocytes.

II. Areas composed of capillary blood-vessels filled with red blood-cells and leukocytes and having extremely thin walls.

III. Areas containing small blood-vessels, with considerably thickened walls.

IV. Portions of the tissue containing whorls and plates of calcareous concretions (Fig. 6).

(*b*) Cyst: Contents of cyst 2 c.c. of serous fluid tinged with blood, containing a few polynuclear leukocytes, a number of mononuclear cells and cocci in pairs. No tubercle bacilli were found.

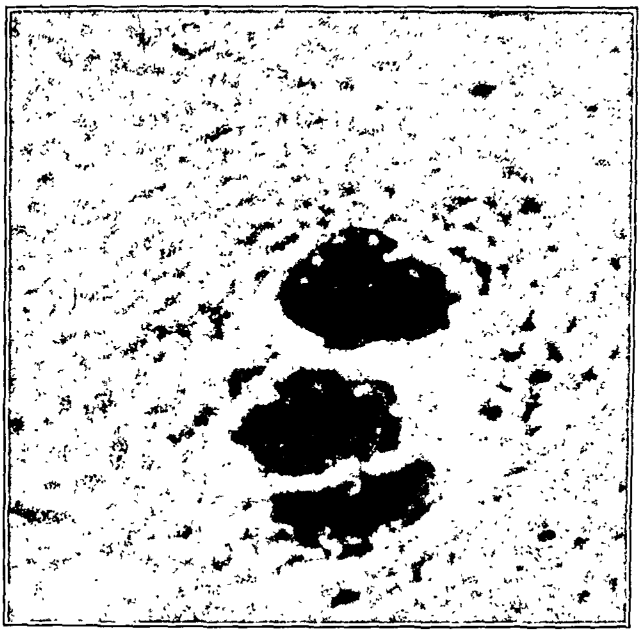

Fig. 7.—Calcareous deposits.

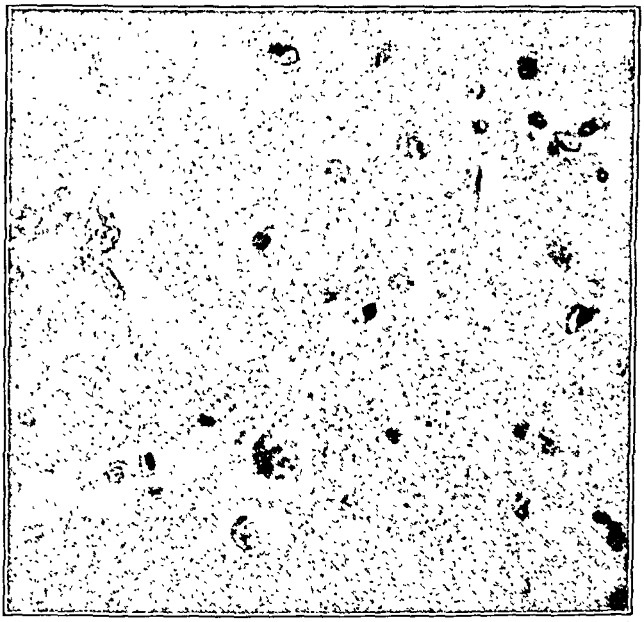

Fig. 8.—Normal brain tissue.

2. Degenerated material: (*a*) Smears show many polynuclear leukocytes, many large and small mononuclear cells, large cells having large round or oval nuclei and distinct protoplasmic processes, i. e., nerve cells, and many cocci in pairs and in short chains. No tubercle bacilli were found.

(*b*) Slides show cellular destruction, infiltration with polynuclear leukocytes and red blood-cells, deposits of calcareous material (Fig. 7).

3. Loosened brain tissue: Slides show nervė cells and neuroglia of the cerebrum (Fig. 8).

Summary.—1. The glioma involving the optic radiation on the right side explains the homonymous hemianopsia.

2. The extensive softening and gliomatous infiltration in the region of the right thalamus explain diminished pupillary reflexes on the blind side, inequality and varied reactions of pupils.

3. The cyst was in a position to make direct pressure on the color center of the left occipital lobe and, since the symptoms developed in the order in which color, natural objects, and light centers are arranged, this pressure (since it affected the visual centers of the temporal half of the left retina more than those of the nasal half of the right retina) could explain the unilateral hemichromatopia, providing the falx cerebri would allow transmission of such pressure.

4. The increased intracranial pressure explains the choked disks, hemorrhagic retinitis and headaches.

5. The calcareous deposits suggest slow development.

6. The postoperative paralysis of the left side was caused by pressure of motor area on edge of trephine opening.

7. Post-mortem changes, or contamination at time of autopsy, could explain the presence of micro-organisms in pathologic specimens, since there had been no indication of infection.

8. Death was undoubtedly due to the extension of degenerative changes to the larger blood-vessels in the brain.

ENDEMIC MALTA (MEDITERRANEAN) FEVER IN TEXAS

FURTHER NOTES ON ITS DISTRIBUTION AND PROBABLE SOURCE WITH REPORT OF ADDITIONAL CASES

THIRD PAPER

ERNEST R. GENTRY, A.B., M.D.,
AND
THOMAS L. FERENBAUGH, A.B., M.D.
Lieutenants, Medical Corps, U. S. Army
[WASHINGTON, D. C.]

At the time of our previous communication[1] on Malta (Mediterranean) fever in Texas, in which we reported the isolation of the *Micrococcus melitensis* from two patients ill of continued fever, it was known to us that other cases existed in the vicinity of Langtry, Texas, and it seemed highly probable that the disease had a much wider distribution.

The recent work of the British Mediterranean Fever Commission[2] has conclusively shown that in the Island of Malta Mediterranean fever is almost entirelly contracted through drinking the milk of infected goats. All the cases observed by us had given a history of drinking goat's milk or of being actively engaged in the goat-raising industry. In view of these facts, it was decided to make some study of continued fevers in the principal goat-raising sections of the state, to ascertain, if possible, whether some of the cases diagnosed as atypical typhoid fever might not be cases of infection with the *Micrococcus melitensis.*

From Langtry, where the field laboratory was located, visits were made east and west, through the principal goat-raising sections of the state, embracing an area approximately 300 miles along the Rio Grande and extending 90 miles to the north, including the Nueces and lower Pecos River countries. This section of the border is covered with ranges of low undulating hills, traversed by many rocky cañons, arid and barren for the most part and covered with a desert vegetation. For the past thirty-five years the raising of goats has been the most important, and indeed, in some places, the only industry of the inhabitants.

Careful inquiries through this section elicited the information that for many years there has existed, principally in the Nueces and lower Pecos River countries, a continued fever characterized by frequent relapses, pains in the joints and a very low mortality. This fever has been known to exist in Edwards county, at the head of the Nueces River, for a period of at least twenty-five years. It has been known there as slow fever, continued fever and, occasionally, by the significant term of goat fever.

During the summer of 1894 there occurred in the practice or under the observation of Dr. Robertson of Rock Springs about twenty-five cases of continued fever in the Nueces River cañon. The disease ran through whole families and occurred almost entirely in families that had goat pens immediately surrounding the houses. In many of the cases the fever ran for several months, with frequent relapses. Joint symptoms occurred in many instances and often the patients were not able to walk for several weeks. Dr. Robertson was unable definitely to determine the nature of the fever, but believed that he was dealing with a fever different in many respects from typhoid. Since that time he has each year treated a few patients with an affection which he recognized as a fever of similar type.

More recently Drs. Eads and Rogers of Barksdale have treated patients each year with cases of continued fever, in which the symptoms did not correspond clinically to those of typhoid fever. This report includes two cases which occurred in their practice during the present summer.

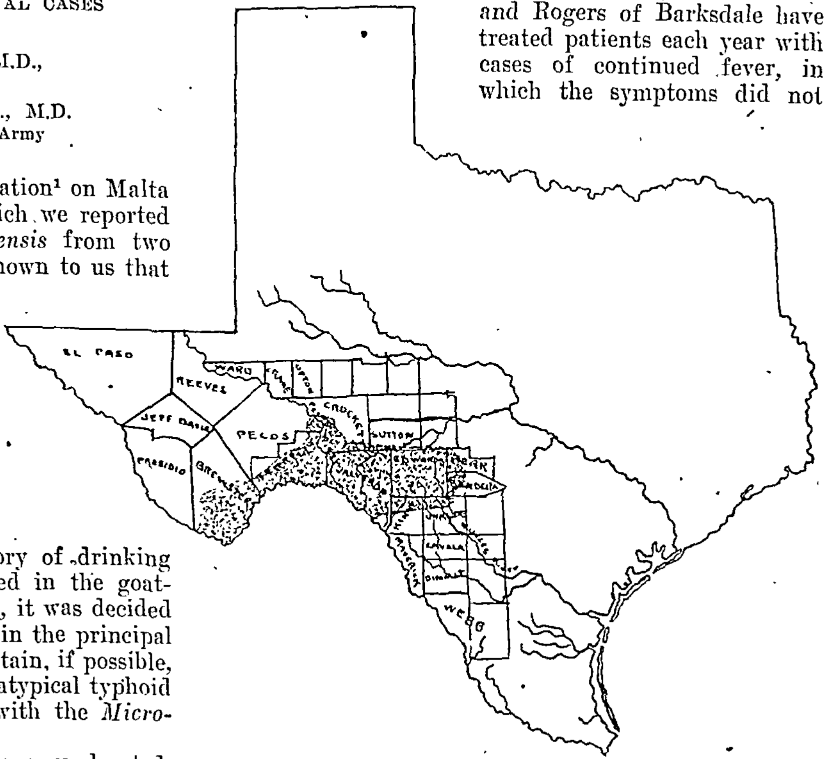

Fig. 1.—Shaded portion of map outlines the principal goat-raising section of Texas, and also represents the area of endemic Malta (Mediterranean) fever.

Many people have believed that the disease was in some manner contracted from goats and occasionally have applied to it the term "goat fever." It has also been called "dust fever," on the theory that it came from working in dusty goat pens. Since the disease is more prevalent during the months of May, June and July, when the prevailing wind is from the south, some of the goat-herders have located their goat pens on the north side of their houses to avoid the dust. The Mexican goat-herders have long believed that slow fever was due to drinking unboiled goat's milk and for this reason, and also because it improves the taste, practically all Mexicans drink only milk which has been boiled.

---

[1] THE JOURNAL A. M. A., Sept. 9, 1911, p. 889.

[2] Reports of British Mediterranean Fever Commission, 1905-7.

It is thought that the disease appeared in the Pecos River country about ten years ago, and it has been known there as slow fever or Rio Grande fever. Owing to the fact that the country is very sparsely settled in that locality the disease has failed to attract much attention, but it is certain that a few cases have occurred there each year for several years past.

The following cases of infection with the *Micrococcus melitensis* were found at Langtry, Barksdale and Rock Springs:

Blood-examination, July 25:

White blood-cells, 6,400.

Hemoglobin, 75 per cent.

Differential count, per cent. (500 cells):

Polymorphonuclear neutrophils	45.
Small mononuclears	47.6
Large mononuclears	4.4
Transitionals	2.2
Eosinophils	.8
Mastzellen	.0
Nucleated reds	.0
Parasites	.0

Centrifugalized specimens of urine were plated out several times on glucose-nutrose-litmus-agar, but no colonies of *M. melitensis* were found.

Case 3 (Also previously reported[3]).—The patient, K. E., has had no subsequent relapse and is feeling well.

Case 4.—On July 20 a second agglutination test on Patient 4, R. E.,[3] with *M. melitensis* gave positive agglutination at dilution of 1/160 in thirty minutes. Normal control 1/40, and *B. typhosus* 1/40, negative in one hour.

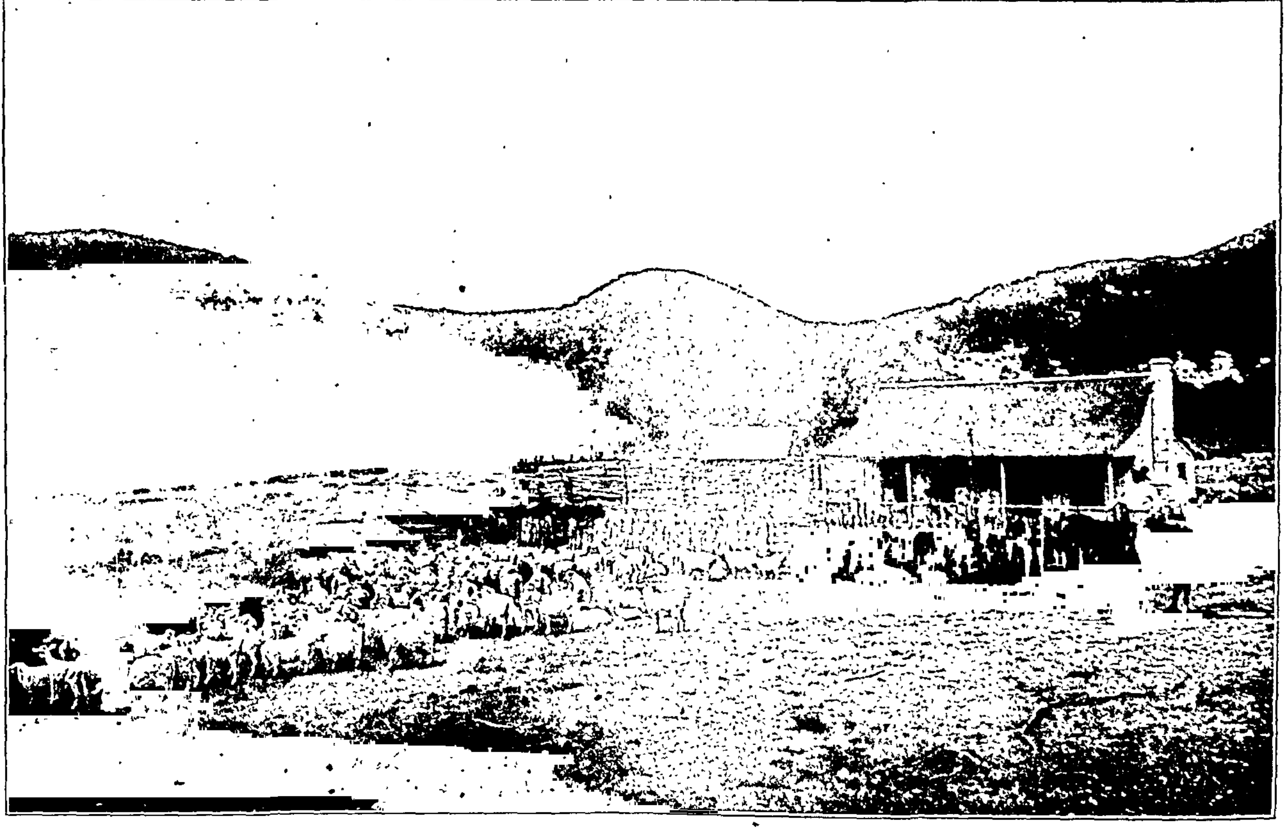

Fig. 2.—Typical goat ranch on a tributary of the Nueces river, near Barksdale, Texas, showing dusty bedding-ground of goats in front of the ranch house.

Case 2 (Already reported[3]).—The patient, L. E., returned to Langtry July 10. When seen at the army laboratory July 14 he was very pale, but not emaciated; temperature normal.

The blood-serum July 19 gave a positive test of *Micrococcus melitensis* in dilution of 1/100 in fifteen minutes.

July 21 the patient relapsed for the fourth time with a temperature of 103 F. He complained of pain in left shoulder, headache, earache, loss of appetite, obstinate constipation and abdominal distention. The fever gradually decreased and the temperature became normal again July 26. No relapse since and patient appears well.

Case 7.—J. E., Langtry, Texas, aged 55, goat ranchman, father of Patients 1, 2 and 3, 4 and 5 had "typhoid-pneumonia" at 5 years of age, and malaria at 21. He became ill June 20, 1911, with headache, pains in bones, epigastric tenderness, pains in neck and back; some cough and slight amount of thick, glairy sputum; temperature ranged from 98.6 to 99 F. in the morning to 101 to 102 F. in the evening for about two weeks; returned to normal July 5; severe pains in right shoulder during second week of disease; bowels constipated; appetite good.

The patient had no relapses and did not go to bed during the course of the fever.

July 19 agglutination test was positive with *M. melitensis* at dilution of 1/50 in thirty minutes.

Case 8.—The patient, J. I., Langtry, Texas, aged 21, was a goat-herder. Father and brother suffered with similar symptoms at about the same time. They had fever for several months with frequent relapses and joint pains. Patient became ill in April, 1909, with headache, chilly sensation, and pains in back of the neck; went to bed after fifteen days of fever. Temperature ranged from 101 to 103 F., with evening rise and morning remissions, and with profuse sweating at night. Patient had five relapses with an interval of three or four days of normal temperature between them. Fever lasted about two months. In each attack when the temperature began to fall, patient suffered severely with pains in back, hips and shoulders. There was obstinate constipation.

---

[3] The Journal A. M. A., Aug. 26, 1911, p. 730. Cases 1 to 5 were reported in this first paper and the detailed histories will not be repeated. Case 6 was reported in The Journal Sept. 9, 1911, p. 889.

Agglutination test July 19, 1911, two years after attack, gave positive test of *M. melitensis* at dilution of 1-40 in one hour. Controls negative.

Case 9.—E. B., Langtry, Texas, aged 22, goat-herder, whose brother and father suffered with similar disease during same year, became ill about June 1, 1907, with fever, headache, pains in back of neck and sides. Fever ran an irregular course lasting about two months. At times patient had no fever and would get up and around for several days; suffered with severe pains in shoulders, knees and hips; no pain in wrists and ankles; profuse sweating at night and obstinate constipation.

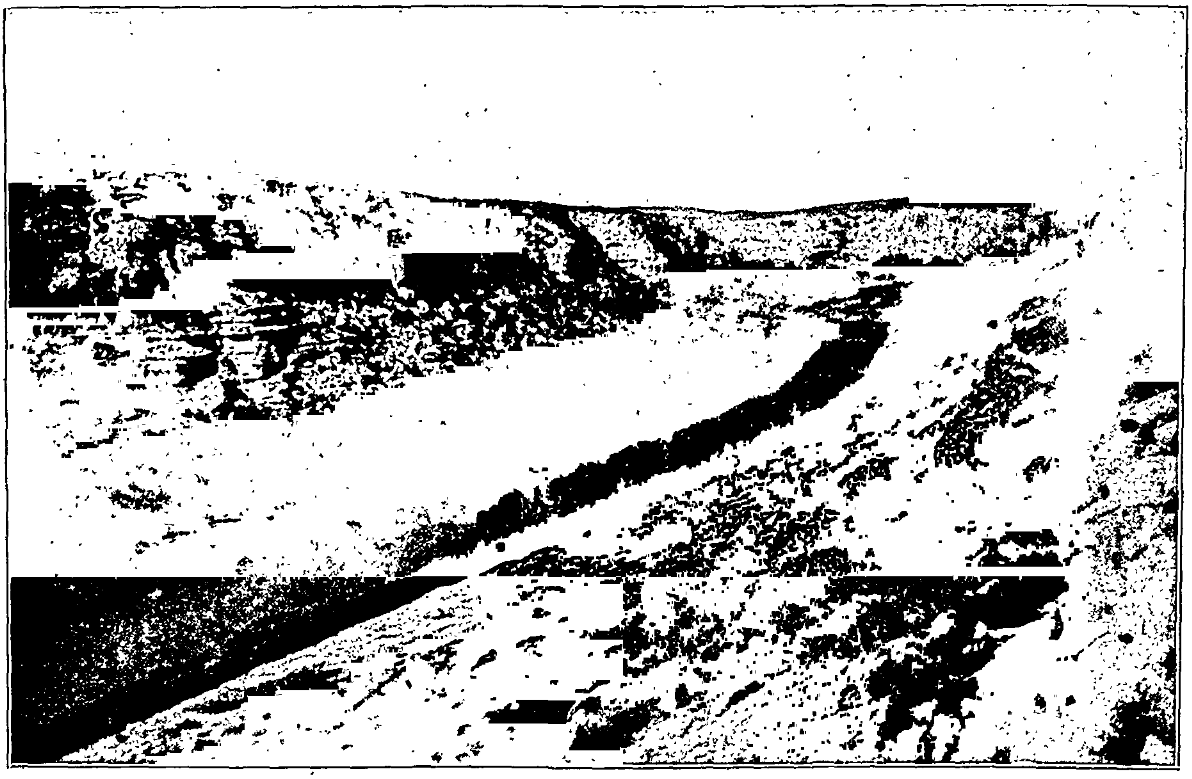

Fig. 3.—The Pecos River Cañon, near Langtry. A typical view in the goat-raising country of Texas. For miles on either side of this river the country is rocky, arid and barren, and covered with a desert vegetation.

Agglutination test on July 18, 1911, still gave positive test with *Micrococcus melitensis* at dilution of 1/30 in thirty minutes. Controls negative in one hour.

Case 10.—The patient, C. G., Rock Springs, Texas, aged 10, was the son of druggist. Adenoids and tonsils were removed at 7 years of age; patient had typhoid fever in 1910; was sick in bed thirty days. Present illness began May 1, 1911, with headache, general aches and pains all over body; profuse perspiration and obstinate constipation with some abdominal distention. Fever began gradually with evening rise and morning remission ranging from 99 to 102 F. Fever ran until May 10. The patient got up May 15, and returned to school a few days later. Relapsed May 30, with mild continuous fever with evening rise and morning remission, often not higher than 99.6 F. in the evening. Temperature became normal five or six times. During the second attack the patient had severe pains in knee, hip and ankle; some pain in left side during last attack; has had no elevation of temperature since July 5. At present looks somewhat anemic, but feels well. Patient has never drunk any goat's milk, but has often played in dusty goat pens.

Agglutination test, positive, with *Micrococcus melitensis* on August 1, at dilution of 1/160 in thirty minutes. Controls negative.

Case 11.—I. W., Barksdale, Texas, aged 6, had had no disease previously except measles at one year of age. He became ill May 12, 1911, with headache, malaise, stiff neck, evening rise of temperature and some sweating; appetite good; bowels constipated and some abdominal distention. On June 15, the fever rose to 104 F. and remained at 102 to 104 F. for about one week, then declined somewhat and afterward run an irregular course, at times going as high as 102 F. There were general aches and pains all over the body and in the shoulders, hips and knees; some pain in side at times; fever still present. At time of examination (August 2) it was 100 F.; spleen and liver enlarged. Physical examination otherwise negative. The patient was well nourished and not markedly anemic; had never drunk goat's milk, but had played constantly in dusty goat-pens. There is a goat-bedding ground just in front of the house.

Agglutination test with *M. melitensis* strongly positive at dilution of 1-150 in thirty minutes. Controls negative.

Case 12.—B. R. P., aged 32, Barksdale, Texas, goat ranchman, had influenza and bronchopneumonia three years ago; made a good recovery; taken sick May 1, 1911, with malaise, fever, headache and pain in back of neck; felt well in the morning, but very feverish toward evening, when the temperature would rise to 102 to 103 F.; had harsh constant cough and distinct dulness over bases of both lungs; lungs seemed filled up with mucus, and he spat up thick, glairy sputum, which was never blood-tinged. The cough lasted about fifteen days; spleen occasionally palpable; fever lasted until May 15, but returned May 25 and lasted until June 21. The temperature ranged from 100 to 103 F.; bowels were tympanitic and there was some diarrhea. The temperature fell to no[illegible]r about five days, but the fever returned again June 27 a[illegible]asted until July 6, ranging from 100 to 102 F. There was normal temperature again for four days. The fever returned July 10 and ran an irregular course since to the time of this report, ranging from normal in the morning to 100 F. in the afternoon. Bowels became very constipated and when moved with castor oil there were occasionally small sloughs of mucous membrane and a few flecks of blood. There was some epigastric tenderness. The spleen and liver were slightly enlarged and tender, and at times the patient complained of pains in the left side of the chest, which were relieved by a mustard plaster; had pain in the right shoulder, hip and elbow, and constant occipital headache. The patient worked constantly with goats and the goats were bedded all around the house.

Agglutination test August 3, 1911, was strongly positive with *Micrococcus melitensis* at dilution of 1/160 in thirty minutes.

Controls were negative.

On September 2 patient still had some fever and had been suffering severely with pains in shoulders, hips and knees.

BACTERIOLOGIC INVESTIGATION ON GOAT HERD WHICH WAS THE PROBABLE SOURCE OF INFECTION AT LANGTRY

In order that the source of infection might be definitely ascertained, if possible, in the cases of Malta fever occurring at Langtry, it was necessary to make a careful examination of the goat herd from which the milk used by Patients 1 to 4 had been obtained. Unfortunately, circumstances prevented this being done in a thorough manner, owing to the fact that at the time of our arrival at Langtry the goat herd was being transported, one-third to New Mexico and the remainder to an inaccessible range thirty miles distant. The herd consisted of about 1,500 goats (divided approximately as follows:

Pure Maltese	100
Spanish and mixed	400
Angora	1,000

Twenty-three female goats were examined with the following results:

Goat.	Serum Dilution.	Result.	Time, Minutes.
1. Maltese	1-20	—	50
2. Maltese	1-20	+	30
	1-40	—	50
3. Spanish	1-20	—	50
4. Angora	1-20	+	30
	1-40	—	50
5. Angora	1-20	+	25
	1-40	+	30
	1-80	—	50
6. Maltese	1-20	—	60
7. Maltese	1-20	+	20
	1-40	—	60
8. Angora	1-20	—	60
9. Angora	1-20	—	60
10. Angora	1-20	—	60
11. Spanish	1-20	—	60
12. Maltese	1-20	+	20
	1-40	—	60
13. Maltese	1-20	+	20
	1-40	—	60
14. Maltese	1-20	—	60
15. Maltese	1-20	—	60
16. Maltese	1-20	—	60
17. Angora	1-20	—	60
18. Maltese	1-20	—	60
19. Angora	1-20	—	60
20. Angora	1-20	—	60
21. Maltese	1-20	—	60
22. Maltese	1-20	+	30
	1-40	—	60
23. Angora	1-20	+	30
	1-30	+	45
	1-40	—	60

Thus eight out of the twenty-three goats (34.7 per cent.) agglutinated the *M. melitensis* completely at a dilution of 1/20, two of the eight going also to 1/30 and one at 1/40 in one hour. The milk of those giving a positive reaction at a dilution of 1/20 was centrifugalized and the sediment plated out on glucose-nutrose-litmus-agar and incubated for four days at 37 C. All plates proved negative for *M. melitensis.*

The Zammit milk agglutination test [4] on the milk of all twenty-three goats was negative in every case.

CONCLUSIONS

1. Malta fever is endemic throughout the older goat-raising sections of Texas.

2. Although typhoid fever is prevalent throughout these sections, we believe that careful serum tests will show that a large proportion of the cases diagnosed as atypical typhoid fever will be found to be suffering from infection with the *M. melitensis.*

3. All cases of Malta fever found have occurred in territory devoted to goat-raising and all patients either gave a history of drinking unboiled goat's milk, or were actively connected with the goat-raising industry.

4. While we have not yet found the *M. melitensis* in the milk of goats, the positive serum test obtained in 34 per cent. of goats examined points strongly to this animal as the source of infection.

A CASE OF SPOROTRICHOSIS

RALPH C. HENDERSON, M.D.
ERIE, KAN.

Patient.—W. H., a farmer, aged 19, weight 185, height 6 feet 1 inch. Father, aged 56, mother 51, two sisters, 26 and 15 respectively, and one brother 12, living and all in good health. One sister, married, died at the age of 25, cause unknown. Patient never had any previous illness.

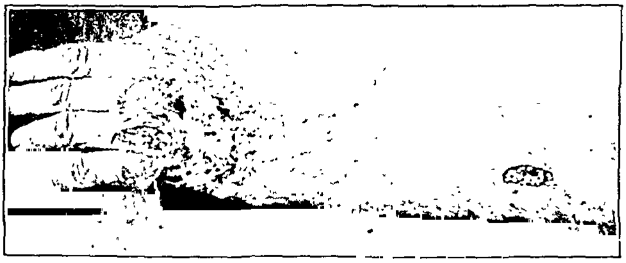

Fig. 1.—Initial lesion on hand and the course upward along the back of forearm.

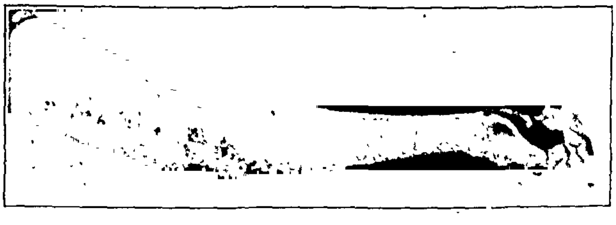

Fig. 2.—The course of infection as it passes toward the ulnar side and around the elbow to the inner and under surface of the arm and up to the axilla.

History.—In the early part of March, this year, patient noticed a small pimple on dorsum of left hand between fourth and fifth metacarpals, 1 inch above metacarpophalangeal joint. This continued to increase in size and was opened with a pin and poulticed.

Course.—March 28, the patient came to my office. The lesion appeared as a ragged, depressed ulcer 1½ inches in length by 1 inch in breadth. Extending upward from this, along the back of the forearm toward the ulnar side, and passing around the elbow to the inner and under surface of the arm and thence up to the axilla, the lymphatic vessels were purple and distended, and eighteen or twenty nodules were present along their course, as shown in the accompanying photographs. The vessels were filled with a dark serous fluid, and tension compelled me to make some ten or twelve incisions for drainage. Later they discharged considerable pus. At no time was there pain or rise of temperature.

---

[4] Zammit: Reports of British Mediterranean Fever Commission, February, 1906, Part 4, p. 98.

Treatment.—The usual surgical treatment was employed, with potassium iodid internally. The patient made a slow but uninterrupted recovery, and was discharged July 15.

My friend, Dr. William K. Trimble, pathologist in the School of Medicine, University of Kansas, at Rosedale, corroborated my diagnosis.

REPORTABILITY OF SYPHILIS AND GONORRHEA *

FRANCES M. GREENE, M.D.
CAMBRIDGE, MASS.

The action of the California State Board of Health in declaring syphilis and gonorrhea reportable diseases is the most important step in this relation that has, as yet, been taken in this country. In a word, it places these two diseases where they belong. It is the result of a straightforward, logical, scientific point of view, unbiased and untrammeled by any smaller consideration than that of the public health of this great state and is prompted by the conviction that boards of health and physicians are to a large degree responsible for that public health.

It thus adds another powerful factor to public hygiene and is destined to define more clearly the relation between physician and society.

It is certain to stimulate the unthinking practitioner, whose motto is "the way we did twenty years ago is good enough for me," into a realization that there is a sociologic and scientific progress for the medical profession as well as for every other branch of human endeavor; that, as society develops, the relations of its various parts necessarily change and he who will not see the movement will be swallowed up in it.

Do physicians ever stop to consider the difference between the relation of a doctor to the community in which he lives to-day and even so short a time ago as twenty-five years? To suspect a family physician of error would have been as heterodox as to change one's religion. A consultation was called only as a last resort and then the tone of the whole family was pathetically apologetic.

How many physicians can feel to-day that they stand in such relation to many of their clients? We are living in a scientific age; the tendency to question, the desire to know and understand is felt even by the most ignorant classes. It would be an object-lesson could the physicians who give their time in hospitals and clinics hear the keen analysis of their characters and methods which takes place among their patients in the waiting-room.

The research worker may shut himself up in his laboratory and obtain for us precious knowledge, the result of his devotion, labor and sacrifice. But the practitioner who applies this knowledge must remember that he forms part of the great world in which he lives; he cannot hold himself apart as a dispenser of panacea but he must live in the midst of that world swayed by its justice and injustice, its joys and sorrows, and on him is often imposed, as in this instance of venereal disease, the choice between his personal tendencies, the influence of the individuals who make up his closer life and that greater circle of activity which means the greatest good to the greatest number, the maintenance of the nation and the race.

Professor Wolf of Strasburg, moved by one of those impulses which is akin to genius, at the international conference at Berlin in 1897 for the purpose of taking measures against the spread of leprosy, brought to the notice of the assembled scientists the puerility of their cause as compared with a condition endemic in every country and unattacked. He little thought that his utterance would be the impetus to a world-wide movement.

Within two years, in 1899, the first international congress for the purpose of combating venereal disease took place in Brussels. The second followed in 1902. National societies were formed in Belgium, France, Germany, Austria, Denmark and the United States.

A close study of the proceedings and work of these societies shows that, except in England, Norway, Sweden and in Denmark as late as 1906, the only measures taken against the spread of venereal disease was the so-called *réglementation* or compulsory examination of prostitutes. In Germany, France and Austria *réglementation* still obtains, although its advocates acknowledge frankly that the system is inefficient and unreliable. They take refuge in the weak statement that a poor system is better than none.

The first European country to make and consistently carry out laws governing venereal disease was Norway. The syphilization of the army and the rapid and intense spread of the disease among a primitive peasantry caused it to assume the character of a contagious disease, pure and simple, with a very small percentage of infection by sexual contact.[1]

In 1774, '79 and '92 treatment of venereal disease was made compulsory. The point of view having been established that these were not shame diseases made it simpler than elsewhere to develop hygienic measures.

In 1860 a law was passed making hospital treatment compulsory on an order of the sanitary commission and classing them with other infectious diseases.

In 1888 regulation of prostitution was abandoned and sane laws covering hygiene and morals established.[2]

In 1901 still more stringent laws were passed covering isolation and treatment.[3]

Sweden, suffering from the same conditions as Norway, as early as 1817 made the treatment of venereal disease compulsory and at the cost of the state. For this purpose a new tax was provided for, called, since 1873, tax for the sick (*Abgabe für Krankenflege*).

---

* Read in the Section on Preventive Medicine and Public Health of the American Medical Association, at the Sixty-Second Annual Session, held at Los Angeles, June, 1911.

[1] Finger: Ztschr. f. Bekämpf. d. Geschlechtskrankh., Leipz., v, part 12. The same condition obtains in Russia to-day, where to 7 per cent. of genital infection 93 per cent. extragenital is found. In fact, there are villages where no inhabitant escapes.

[2] In 1888 the laws regulating prostitution in Christiania were rescinded. 1. Examination and treatment were made easily obtainable for those who demanded it. 2. It was made the duty of every physician to endeavor to discover the sources of infection. 3. When necessary cases were reported and isolation in hospitals secured. Free clinics were established and, although there were 5,000 known prostitutes, 20,000 annually received treatment in these free clinics. Möller: Ztschr. f. Bekämpf. d. Geschlechtskrankh., Leipz., v, part 7.

[3] Dec. 2, 1901 (after the first congress). It shall be the care of the state:

Sec. 5. To see that the syphilitics be placed in hospitals when found necessary by the sanitary commission.

Sec. 6. Every venereal patient who does not provide himself with proper medical attendance or who fails to follow the physician's orders may be sent by the sanitary commission to the hospital and detained there until cured, or at least the danger of infecting others is materially lessened.

Sec. 7. If syphilitics are allowed to leave the hospital in a condition which is liable to infect others, the board of health must be notified. The patient will be obliged to report himself for examination at stated intervals or present a certificate which shows that he is under the care of a reliable physician. . . .

Sec. 13. If a syphilitic, still in that period of disease in which infectious symptoms might be feared, gives up treatment, physician must notify the health office. Finger: Ztschr. f. Bekämpf. d. Geschlechtskrankh., Leipz., v, part 2.

Inspectors for the provinces were appointed whose duties were carefully defined by the law.[4] Seved Ribbing is quoted as saying that it had never come to his knowledge that the people of Sweden felt these measures as inimical to personal freedom. On the contrary, the persons who have innocently or ignorantly fallen victims to the disease are thankful to the authorities. *Réglementation* was, however, still in force in Sweden.

In 1903 the Swedish government appointed a committee to deliberate over the legal measures to be taken against prostitution and its social and sanitary evils.

After seven and one-half years of deliberation and investigation it has declared itself against *réglementation*.[5]

Denmark, in 1906, rescinded the law regulating prostitution and substituted sane general laws calculated to reach every side of the evil.[6]

It will thus be seen that under circumstances of public danger these northern countries were able to establish laws both humane and thorough. Compulsory report is demanded but the privacy of the individual is respected as long as he submits himself to proper treatment and observes such rules as prove that he respects the community in which he lives. A glance at the laws in force in Prussia and Austria will show the difference in method.

By an edict of 1835, physicians in Prussia were required to report dangerous cases of syphilis to the police.[7] To a certain extent, at least as far as the power of the police is concerned, these laws are in force to-day.

Harthüng, head physician in a Breslau hospital for venereal disease, made the following statement at the international congress in Brussels, 1902: When he is convinced that his out-patients have sexual intercourse against orders of the physician, or are otherwise dangerous, he asks them to enter the hospital for treatment. If they refuse they are arrested and brought to the hospital by the police. If they leave without permission, they are again returned by the police.

---

[4] Article 28. Measure against venereal disease.

1. If a physician, following the order of the authorities, examines a person supposed to have venereal disease, it is his duty to report to the magistrate the name and address of the patient if said patient cannot show within a short period, named by the physician, that he has placed himself under satisfactory medical treatment. It is also the duty of the physician to inform the magistrate, when he deems it necessary, that the patient should be sent to a hospital, and the magistrate must report the same to the physician as soon as it happens. If a patient refuses examination, the authorities must invoke the law.

2. In order to prevent the spread of venereal disease the county physician must do his best to discover the source and method of infection, as well as to further the admission into hospital.

The physician is also bound to inform the authorities if the patient refuses treatment, does not faithfully follow orders of physician, or when there is danger of further infecting others. Finger: Ztschr. f. Bekämpf. d. Geschlechtskrankh., Leipz., v, part 11.

[5] "The objections which are brought to bear against regulation from a social, moral and legal point of view are so formidable that the usefulness which, from a sanitary point of view, it might possess is not allowable as a consideration for its retention or abolition.

"Any prophylactic measure which so offends the sense of justice cannot be maintained by reason of so lame a recommendation as that it is of some, although not great, usefulness.

"Only under conditions that would prove regulation a sanitary necessity could there be any consideration of its retention. Since the committee can admit no such presumption, it cannot consent that this form of law against contagious venereal disease be further used in our country."

The committee recommended certain new laws, such as punishment for the infection of another, in severe cases two years' imprisonment; the duty of physician to search for the source and the conditions under which infection takes place; punishment to four years of forced labor for procurers; making infectious diseases grounds for divorce. Furthermore, it was recommended that professional prostitution be forbidden and such persons be made amenable to the law as vagabonds. Mitt. d. Deutsch. Gesellsch. z. Bekämpf. d. Geschlechtskr., April, 1911.

[6] Danish law of March 30, 1906, rescinds the law regulating prostitution. New laws:

Article 1. Police regulation of professional prostitution is repealed.

The police have the right to interfere (take steps against persons who practice this trade) according to the law against vagabonds.

Article 2 of the law against vagabonds can be used only after due warning has been given. This gives the police the right to bring before a judge vagabonds or others who cannot show that they have means or regular work; he may order such person to get work or provide work for him.

If the said person does not appear or does not follow the order to work, they may be punished by forced labor. However, the vagabond law can be put into effect only after a preliminary warning.

Article 2. Whoever provokes, tempts or entices to prostitution, whoever openly leads a life of indecency, whoever gives rise to open scandal or is a nuisance to neighbors, will be punished by imprisonment; under aggravating circumstances or repitition or offence, by forced labor. Under extenuating circumstances the punishment may be a fine.

The same punishment will be inflicted on any professional prostitute who keeps in her house any child over 2 years of age or who receives for immoral purposes young people under 18 years of age.

An admonition may precede punishment in any of the above cases in which it is a first delinquency.

Article 3. It is forbidden to keep houses of prostitution. Whoever disobeys this law is punishable with imprisonment, the house of correction or hard labor.

Procuring amendable to same punishment.

Whoever for pecuniary gain allows prostitution in his dwelling or rents rooms not to permanent roomers but to encourage prostitution, or who shelters girls under 18 who prostitute themselves, will be punished with imprisonment or hard labor.

Repetition of the offence may be punished by two years of forced labor in a penitentiary.

It is forbidden to advertise publicly, to expose or export articles for the purpose of preventing the consequences of sexual intercourse or to offer the same for sale to strangers or promiscuous individuals.

Article 4. Any person who has sexual intercourse under the conditions set down in Article 181 of the Penal Code will be punished as provided for in Article 181 if through such intercourse another becomes infected and institutes a suit within one and one-half years after the diagnosis of the disease.

If the person infected in such intercourse was ignorant of the danger of such infection, the author of the infection must pay not only the cost of treatment but damages (compensation) as well.

Article 5. Individuals with infectious diseases have the right, though they may have the means to pay for treatment, to derive such treatment from government sources. On the other hand, they are obliged to submit to this treatment; in every event must the individual be under such medical care as offers a sufficient security.

If the venereally infected individual finds himself so placed that he or she cannot prevent infecting others, or if he does not obey the rules of prophylaxis which have been prescribed, he must be sent to a hospital. The prefect of the police in Copenhagen and the president of the police are the authorities in such cases.

Neglect of these duties are followed by correction from the above officials. If these remain without results the police step in.

Individuals who are in receipt of public charity must be treated in hospital when subjects of venereal disease.

Article 6. If during, or at the end of, treatment the physician considers that in view of the danger of infecting others the patient must still be kept under observation, the physician must demand of the patient to present himself at stated times, if the patient does not bring a written proof that some other legitimate physician has him under treatment. The necessary proof can be obtained from the government physicians and the municipality.

If the patient does not obey this law, or if the physician wishes to give up the case and the patient does not appear with a certificate stating that he is under the care of another physician, then the official physicians must be informed and the aforesaid patient must be commanded to present himself at the public dispensary.

Article 7. The physician is commanded to inform the patient of the infectious character of his disease as well as the punishment which would follow his infections of another. Particularly must he be warned against marriage as long as the danger of infection exists.

Article 8. The physician is ordered to report weekly the number of persons who come under the head of Article 6. Patients who give the physicians false names, sheltering positions or addresses are punished.

Article 9 treats of the infection of a healthy nurse through a sick child or a healthy child by means of a sick nurse.

Article 10. Whoever is accused of crime against Articles 1, 2, 4 or 9 of these laws or 181 of the Penal Code must be asked on an order of the police to submit to examination by a physician. In case of refusal, if the proof of the accusation is sufficient, the law must force the examination.

Article 11. The medical examinations in cases above described shall be made by the public district or city physician or by a specially appointed visiting physician. The compulsory visit shall be made by a physician of the same sex as the accused (unless it is immaterial to the accused) if such is to be found in the same district, so that no delay may occur, and if the said physician is willing to undertake such examination.

Article 12. The official physician must treat all venereal patients free of charge.

Article 13. If the official physician deems it necessary, the patient must present himself at the times stated by physician. Neglect in doing so is punished first by fines and later by intervention of the police.

Article 14. Those who are treated free in hospitals may not leave such institutions without the consent of the physician.

Article 15 forbids proprietors of hotels or rooming-houses to make use of prostitution for the service or amusement of guests.

Article 16 gives the various grades of punishment and defines venereal disease and its various forms.

Article 18. The law shall go into action six months after date, Oct. 11, 1906. All earlier laws governing prostitution thus become null and void.

[7] Edict of 1835. Prussia.

65. When, according to the opinion of the physician, secrecy as to the disease will lead to adverse consequences either to the diseased person or to the community, he is obliged to report the case to the police. Failure to do so makes the physician amenable to a fine of 5 thaler, with a double fine for a second offense.

69. It is the duty of the police to see to it that physicians, especially those employed in hospitals, make every effort to inform the police of the sources of infection in order that careless and indigent persons may be prevented from further spreading the evil (Finger).

In the Rudolf Virchow Hospital in Berlin, while other diseases are treated in pavilions of twenty beds, two buildings, four stories in height, are devoted to venereal disease. It is significant that each is surrounded by a stout wall and a locked gate.

In Austria the few laws which apply have been inspired by the same spirit.

The most cursory glance at the different methods of these countries will show why in Norway, Sweden and Denmark, in spite of the appalling conditions of a hundred years ago, there is a steady decrease of venereal disease, while in France, Germany and Austria venereal disease shows no appreciable decrease. These governments will not admit that they have to deal with a wide-spread contagious disease, the control of which should be in the hands of a health commission, but still rely on the police to carry out a number of paradoxical and one-sided laws which are utterly unfitted to control disease.

Another important point in the laws of these northern countries is that concerning the investigation of the sources of infection.

In the study of a question so difficult of solution, so momentous in its importance, one seeks in all directions for the support of some known experience.

Dr. Magnus Möller of St. Goran, Stockholm, gives some interesting data based on the questioning of 661 patients, mostly artisans and laborers, concerning the sources of their infection. He was struck with the general willingness to give full information, when the questions were tactfully put and the seriousness of the investigation made evident.

At least 20 per cent. of the number gave information sufficiently clear to make investigation of the source possible; 67.7 per cent. could give no information, having been drunk at the time of infection. In one-quarter of the cases was the cause traced to controlled prostitutes. A number of cases were often traced to one individual.[8]

The secrecy maintained in regard to syphilis and gonorrhea has led to a neglect of these diseases by the general practitioner. A physician does not follow closely the woman patient whom he dares not warn of the true nature of her disease.

The symptom once eradicated, the patient drops from view and is still exposed to further ravages of the disease. The physician is deprived of clinical observation, valuable not only to his own further development, but to the health of the community. Diseases neglected in treatment will be neglected in study. It is the constant cry of specialists that the knowledge of the general practitioner in the matter of venereal disease is lamentably defective.

Professor Finger has rightly said that we shall never make progress in the treatment of syphilis and gonorrhea until the public has been made to understand that instead of being ashamed of and not fearing these diseases, they should not be ashamed of but fear them. The public can be made to understand this only by placing syphilis and gonorrhea where they belong, with the other infectious diseases.

Where these diseases are reportable, both physician and patient are placed in a position of joint responsibility as regards the public health. The physician's interest is kept alive. It would be of incalculable educative value for the man who is carrying about with him a disease to know that it is regarded, not as a concomitant of manhood, but as a pathologic condition and to be forced by public measures to consider himself a menace to others whether he evades the law or not. If, as in other infectious diseases, the law is made to cover the seeking and elimination of the sources, we shall have the whole matter of scientific treatment in our hands.

The theory has been advanced that there is only one thing to do: wait for science to find a remedy. There has been a remedy in existence since the sixteenth century. It was found by chance but properly used is good. Salvarsan may or may not fulfil its promise. It is already much talked of as an excellent adjunct to mercury.

How can the public be made to feel the necessity for treatment and how can they be saved from quacks? A law should exist making treatment of such diseases by any but legitimate physicians a criminal offence. The quack is already making use of scientific discovery and social progress.

After our first public meeting in San Francisco, a decided difference crept into the wording of quack advertisements. It was easily discernible that they were stealing our thunder.

No sooner was the discovery of salvarsan made public property than an enormous advertisement appeared in an Austrian paper inviting the public to visit an exhibition of "Professor Ehrlichhata's Cure 606." "The Greatest Discovery the World has Ever Seen. Entrance 10 pf. Fridays for ladies only." The usual panoptikum wax figures were shown with the inscriptions: "Before Treatment." "A Few Hours After Treatment with Herxherimers Reaktion." "Several Days After, Cured."

There are only two ways for the medical profession to protect itself from these parasites: appealing to the law and assuming a definite attitude regarding this question.

For those who have studied the psychology of the crowd, it is not so difficult to see the reason for the success of the quack. He talks out loud, very loud. He makes a great show of being open in his methods. The people do not go to quacks for the treatment of venereal diseases alone. They fear and distrust the knowledge of the physician which he dares not impart. It smacks too much of magic and so often does not fulfil its promise.

Let the public realize that we range ourselves on the side of law, order and justice. Let the physician respect the confidence of his patient but let him scorn the confidence of the man who would deliberately do a criminal act and make him a party to it. There may be those who will prate of professional secrecy, but in their souls they will esteem and admire the man who can rise above an antiquated tradition in order to save even one woman from the results of either one of these dread diseases.

The medical profession stands in a position of peculiar delicacy in this matter, being the only class outside the handful of social workers, who have come in contact with the recognized results of prostitution. Physicians in the world and of it have shared the universal error of secrecy. We may safely say—until now an error. We may also confidently assert, speaking for the world, or rather for those who make the world worth the while and who must ever be the mouth-piece and the guide of the physically, mentally and morally unfit, that the physician who now lends himself to the policy of secrecy makes himself the accessory to a crime.

---

[8] A number of cases were often traced to the same source of infection: thus, three cases of gonorrhea to the same controlled prostitute. Three cases of primary syphilis (two boys of 16) to the same source. Four gave the same woman as cause (controlled prostitute. (Magnus Möller, Stockholm. See Note 2.) In Norway during a period of nine years, by means of report and search for the source, 546 women of all ages, of whom 262 were syphilitics, came under the care of the sanitary commission. Strange to say, only twenty-two syphilitic men were discovered in this manner. Italy must be mentioned as not only treating all who come gratis, but providing medicine as well. This law, *Lex Crispi*, was due to the efforts of Prime Minister Crispi.

It is not only his bounden duty to take his public stand for the public good, but it is also his duty to assert his attitude toward those of his profession who through ignorance, mistaken ideals, or absence of professional honor create an opposition which is destined to deprive medical practice of its right to be called a profession.

The moment for half measures is past. The dire physical consequences, with frequent vicious mental accompaniments, come to our notice daily and what do we do about them? We are treated like merchants. Our prescriptions are taken—bills paid or not; our patients neglect themselves or worse—pass on the consequences of their vice—and we shrug our shoulders, pocket the money when we get it and feel that our duty is done.

The members of the international congresses of 1899 and 1902 found themselves face to face with a seemingly insoluble problem. In despair at finding an immediate corrective, and overwhelmed at the universal magnitude of the problem, like little children of larger growth, they turned to the mothers and cried out, "You cannot make us over. See in us the evil effects of ignorance and neglect. Care for our sisters and brothers!" They did, it is true, strike a fundamental note. Reformation of character can rarely begin with the adult.

The horror of economic conditions has been laid bare and willing hands and minds are working in every direction to help the poor to a living chance. But what has the medical profession done? It is now twelve years since the first international congress was held. Societies for the purpose of fighting venereal diseases have been formed the world over, inspired or founded by medical men. In this country the general complaint is that medical men do not uphold them. It is the layman who keeps them going.

It is time that the medical profession rises as one man and does its duty toward the state in which it lives and the nation whose health it is supposed to safeguard. Publicity in this matter of venereal disease is one of the first requisites for its control, as it is for the control of any other infectious disease. Read the findings of the Chicago Vice Commission and ask yourselves if there should be any more temporizing.

If laws demanding a report of every case, without name, be passed; if every discoverable source of infection be controlled regardless of the patient's social position; if adequate hospital and clinical facilities are provided not only for the very poor but for the struggling middle class, the medical profession will be able to say with pride: "We have done our best to inspire public confidence. We have vindicated our right to be the custodians of the public health."

5 Avon Street.

Neglect of the Middle Period of Life.—The rungs at the bottom of the ladder of life are being carefully looked after; those at the middle of the ladder have been neglected; the physical welfare of the man has been lost sight of in the multitude of attempts at prolongation and betterment of the physical properties of the child.—Guilfoy in *Journal American Public Health Association.*

REPORT OF COMMITTEE ON CONTROL OF VENEREAL DISEASE BY A MUNICIPALITY *

When I was asked by the Chairman of the Section on Preventive Medicine and Public Health, Dr. William A. Evans, to act on a committee for the purpose of reporting on the control of venereal disease by municipalities, I accepted without hesitation and for two principal reasons: first, because my associate on the committee was to be Dr. George M. Kober of Washington, who has studied this problem exhaustively and has reported on it, and second, because I have made some study of the question myself and consider it one of the most important problems, as well as one of the most difficult ones, with which the public health official comes into contact and is expected to solve.

There is no need of taking up the time of a gathering of sanitarians by reciting statistics, easily accessible and probably more or less known, to show the prevalence and the ravages of this class of diseases. Such an introduction to the subject would be indicated in a popular address, but may be safely omitted here.

I have written to the health officials of twenty-one of the larger cities, asking what their cities are doing for the control of venereal disease and what, in their opinion, the cities should do. I have received answers from fourteen cities, and they show that in seven nothing is being done, in six some steps are now being taken for the prevention and restriction of venereal disease, and one city, namely New York, is about to start a vigorous campaign, which is outlined by the secretary of the Board of Health as follows:

"As the result of widespread agitation that has taken place in the city of New York during the past few years, the Board of Health has urged on the Board of Estimate and Apportionment the need of making provision in the next annual corporate stock budget for the erection of a public hospital for the care of persons suffering from venereal diseases. In addition, the matter is to be referred to the Medical Advisory Board of the Department of Health and it will be requested to consider the subject and submit recommendations for a comprehensive plan for the public control of all such diseases."

In four of the seven cities in which nothing is being done, the health officers make no recommendations and give no expressions of opinion as to what ought to be done, but in the three remaining cities the health officers are evidently anxious and willing to start activities. They all recognize the value of an educational campaign and all advocate it.

One of the writers, a health officer of a large eastern city, says: "Every city ought to furnish advice to those contemplating marriage. More than this, it should work for the control of these diseases by instituting a program of sex education, beginning with the little child when it first begins to ask questions relating to the origin of its being."

Another letter from a far western city says: "I think, however, that the public should be educated on the importance of this question, as the results are more far-reaching than any one has an idea of."

The third letter from an assistant health officer strongly advocates "a sane method of spreading knowledge on this subject" as the only way to control the diseases. Of the six cities in which some precautionary methods are in vogue, five are taking care of the patients in hospitals, some insist on hospital treatment which is compulsory or nearly so, while others take only such patients as are willing to go to a hospital for treatment. In two cities, special clinics are maintained by the municipality for the purpose of controlling venereal disease. At these clinics cases are registered, patients properly treated and can be kept under observation.

An interesting letter was received from the health commissioner of one of our most prosperous and growing western cities. He deals with the subject from the standpoint of the spread of venereal disease by public prostitutes and relates some interesting municipal history. The former mayor of the city in question established a restricted district, in which all known prostitutes were segregated and then subjected to rigid inspection and police control. On account of the establishment of this district and conditions which surrounded it, a recall election was held and a mayor elected who announced his position in his campaign substantially as follows: "If I am elected mayor I will not allow a restricted district to exist in the city, and furthermore, I do not believe that public prostitution is necessary." The health commissioner goes on to say that the mayor has carried out his preelection promise and that the city is much freer of prostitutes than it has been at any time within the last twenty-two years, and then the writer concludes: "Venereal infection in this city has been reduced to a minimum. Two years ago, the woman's ward in the City Hospital was filled with women suffering from venereal infection. To-day, while we are treating more patients, such diseases are not frequently seen." Although I cannot agree with the doctor's conclusions, I was much interested in his report and am pleased to submit it. There are only two cities from which I have received the information that these diseases are reportable to the board of health. The health officer of Cleveland says: "Venereal diseases are reportable in Cleveland. The law is not strictly enforced, as it is as yet almost impossible, but it gives us the power to order to a hospital any one that we find, for instance, in salesrooms or restaurants, etc., affected with venereal disease." Dr. Evans of Chicago reports that the dispensaries of that city are required to report venereal diseases and that, even without a law requiring this, hospitals are reporting to the board of health, for the most part at least, their cases of venereal disease.

---

* Read in the Section on Preventive Medicine of the American Medical Association, at its Sixty-Second Annual Session, held at Los Angeles, June, 1911.

In Michigan and in Detroit there is as yet no law requiring the reporting of cases of venereal diseases. This is true, not because the public health officials are opposed to having these cases reported, but rather because they believe that it would not be possible at this time to enforce such a law strictly. In order that a sanitary law may be enforced it must be backed by public opinion, and this can be brought about only by a campaign of education. We therefore believe that the first and most necessary step for the control of venereal disease is a vigorous campaign of education which will teach the people something of the prevalence and dangers of these diseases and the necessity of reporting the same.

The physicians, too, must be educated in this respect. Ten years or more ago it would have been impossible to have passed and enforced a law requiring the reporting of cases of tuberculosis, and practically the same objections that were then advanced against such a law are now used against the reporting of these diseases. It is held by the opponents of such a measure that the knowledge of a patient having venereal disease must be kept secret between the patient and his physician. This objection can easily be overcome by inserting in the proposed law, as was done in the case of tuberculosis, a section protecting the records and making it unlawful for the health officer to divulge them.

In undertaking a campaign of education of the masses, the health authorities of any municipality should seek the cooperation of a number of intelligent people who may associate themselves by the formation of a society for sex hygiene or some similar organization. This has been done in Detroit. There has been formed an organization known as the Detroit Society for Sex Hygiene, whose principal object it is to give this subject the proper kind of publicity. Pamphlets have been published and distributed in the workshops, in public schools, among church societies and in other places where it is thought they would do the most good. A number of public meetings have been held in which well-informed speakers have explained the subject to the people. In this way public sentiment is being aroused and it will not be long before it will be possible to obtain a law requiring the reporting of all cases of venereal disease and at the same time it will be possible to enforce such a law.

In the meantime there are some things that a municipality can do looking towards the prevention of venereal disease. In the case of tuberculosis we did not wait for the reporting of all of the cases but rather went in search of them. In Detroit, for example, we employed visiting nurses to make a house-to-house canvass, the primary object of which was to spread the gospel of the prevention of tuberculosis, but incidentally to find cases of the disease that had not been reported and refer them to the board of health for further investigation and action. In the case of venereal disease, we can reach some of the cases, and it seems to us that the practice now in vogue in Chicago and reported by Dr. W. A. Evans, namely, to require the reporting of cases of venereal disease by all dispensaries and hospitals, is a good one. There is no reason why this cannot be done in other communities and it is not likely that hospitals and dispensaries would object to such a requirement. Again we know that in nearly all cities there are a number of prostitutes, and in most cities these women are more or less segregated, and we further know that among this class are to be found a large number of cases of venereal disease. It stands to reason, then, that these women, who are plying a lawless vocation, should be made to report the cases of venereal disease that may exist among their number. In making this suggestion we do not intend to recommend the licensing of houses of prostitution and the regular medical inspection of their inmates. We believe, as has been said by Dr. George M. Kober in his paper on "Diseases Which Menace Public Health and Morals," "that such licensing and medical inspection tend to produce a false sense of security, as inspection is insufficient to prove the absence of disease even in the hands of the most skilled." On the other hand, it is possible to secure the reporting of venereal disease among prostitutes by another method, which has been adopted by the Detroit Board of Health. We accept no certificates of good health whatsoever. The keepers of all houses of prostitution, known to the police, have been notified by the latter that inspectors from the board of health will make occasional visits at these houses for the purpose of examining inmates. These visits are made at unannounced and irregular intervals. Whenever an examiner finds one or more of the inmates ill with a venereal (contagious) disease, the house is placarded. We use a large yellow placard with the one word, "quarantined," printed thereon in large, conspicuous black type. If the keeper of the house or her physician reports the case to us before we discover it, we give the patient the alternative of going to the hospital and do not quarantine the house, just the same as if it were a case of some other contagious disease, for example, small-pox, scarlet fever or diphtheria. The effect of this regulation is that the cases are reported, but the machinery necessary to make it a success is a corps of competent medical examiners and proper hospital accommodations. In Detroit it worked out as follows: Shortly after the adoption of the regulation by the board of health, the health officer made a visit to one of these houses and examined the inmates. One woman suffering with gonorrhea was found, the clinical diagnosis being confirmed by a bacteriologic examination. The house was immediately quarantined and the result was that within a week we had reports of at least twenty cases of venereal disease with requests that the patients be removed to the hospital. We found that our hospital facilities were wanting and accordingly began an agitation for an appropriation for this purpose, which was finally granted in the spring of this year and we hope, within the next twelve months, to have hospital facilities sufficient to carry out the plan.

There is another class of cases of venereal disease, gonorrheal vaginitis in young girls, which can be reached. Many of these cases are found in dispensaries and children's hospitals and would be reported under the Chicago plan; many others can be found in the juvenile courts wherever such institutions are in existence. A juvenile court has recently been established in Detroit and by placing a physician at the disposal of the court for the purpose of examining the girls and boys who come under its jurisdiction, a number of cases have been discovered. I desire to say in this connection that the cases of venereal disease among boys have been very few as compared with those found among the girls.

The maintenance of special clinics by the municipality, such as are reported from two cities, is of great value in the control of these diseases. In Detroit, and in many other cities the board of health maintains one or more clinics for tuberculosis. In these institutions the cases are found and the opportunity is given to the board of health for a visit to the homes of the patients and the possible discovery of additional cases. It has been our experience that the majority of incipient cases are found in this way. The same opportunity for a visit to the homes and a proper inspection may be had in the case *of a special clinic for venereal diseases.* We are about to open such a clinic in the Board of Health Building in Detroit and are hopeful of good results.

It is a striking fact that in my correspondence with the health officials of fourteen cities, only one, in his answer, alluded to the damage done the eyes of the new-born by gonorrheal infection. The suggestion comes from Dr. Evans of Chicago that this side of the problem should not be forgotten, and well we know that he is right. To control ophthalmia neonatorum every city should have effective regulations governing midwives and physicians who attend maternity cases, as well as hospitals and institutions in which such patients can be cared for. Special clinics, known as "mothers' clinics," should be maintained and, besides being in charge of a competent physician, they should be equipped with a corps of visiting nurses whose duty it is to make calls at the homes of the babies and, while instructing the mothers in the general hygiene of the child, they should pay particular attention to the care of the eyes.

In conclusion I would make the following recommendations:

1. The inauguration of a campaign of education, in cooperation with a society specially organized for that purpose.
2. The requiring of reporting of all cases of venereal disease by dispensaries, hospitals and juvenile courts.
3. The requiring of the reporting of all cases among prostitutes.
4. The establishment of special clinics under boards of health for the treatment and control of venereal diseases.
5. The enactment of a law requiring the reporting of all cases by physicians.
6. The establishment and maintenance by the municipality of hospitals of sufficient capacity to care for all highly infectious cases.
7. The establishment of laboratory facilities for diagnostic purposes, such as are had for other contagious diseases.
8. The amendment of all birth registration laws so that births are required to be reported within twenty-four hours.
9. The enactment of laws or regulations for the control of midwives and physicians who attend maternity cases.
10. The enactment of laws requiring the reporting of specifically infected eyes.

Guy L. Kiefer, M.D.,
Health Officer, Detroit.

I concur in Dr. Kiefer's recommendations.

George W. Kober, M.D., Washington, D. C.

ABSTRACT OF DISCUSSION

ON REPORT OF DRS. KIEFER AND KOBER AND PAPERS OF DRS. GREENE AND EATON *

Dr. Herbert Gunn, San Francisco: As chairman of the Committee of Public Health of the County Medical Society of San Francisco, I had occasion to look into this subject very thoroughly. We were asked to pass judgment on it, which later on was deferred; but I took the trouble to go to the venereal disease clinic established in San Francisco, as described in Dr. Eaton's paper, frequently during that time, and also to go around at night with the plain clothes policemen who were in charge of the work under the supervision of inspectors of the clinic. I know, from personal observation, that a definite work is being accomplished there. They have under the control of the clinic now several hundred women; many of those found infected have been checked up in their homes or their places of business, at various hours of *the day* and night, and it has been found that a great many of them are really not doing work when they have been told not to do it. The madam in charge of them, in instances in which they are in regular houses, cannot afford to allow them to do it, because the houses are put out of business for a week on the first offense, or permanently if repeated. One woman was sent to the county jail for sixty days for having disobeyed the orders of the clinician; so that many of them are afraid to disobey. The only thing which I could see which would greatly *improve the work would be the absolute segregation of prostitutes.* Were this possible they could be controlled very much better than they can now. The greatest difficulty is encountered in dealing with the women in cafés or dance halls—women who live, possibly, in apartments and go to these cafés to pick up customers whom they take to a transient hotel, subsequently returning to their apartments. These women are very hard to control, because they move around constantly. I believe, however, that quite a number of them are going to the clinic, while some have either left town or stopped doing work when they were ordered to appear for examination.

As far as the matter of education is concerned, and the dissemination of knowledge on this subject, I think that the establishment of the clinic in San Francisco has done more in that line than anything that was said or done by any of the societies of California prior to its establishment. Every business man in San Francisco at the present time is perfectly familiar with the subject; they are talking about it, and the majority of them, I believe, are in favor of it.

As far as the success of *réglementation* or segregation and the regulation of prostitution is concerned, it is not a failure in all parts of the world; and, furthermore, if it were, is that any reason why it should not be tried again if no better working plan can be devised? In Manila the plan of segregation and inspection has been carried out thoroughly and successfully. The percentage of venereal disease there has materially decreased. Years ago, when I was in the Army, Manila was one of the worst infected cities in the world. Even then, I saw examples on a small scale of segregation and regulation in army posts. In one regiment, nearly 900 strong, over 400 had venereal disease. In one company there were thirty cases of syphilis, nearly all originating from one woman.

The smaller the town the less the difficulty there would be in controlling prostitution. In the larger cities the difficulties are considerable, especially in San Francisco. In the valley towns of California, for instance, it could be carried on with very little difficulty, because practically every prostitute would be known by everyone in town, so they could be readily controlled.

It is said that venereal diseases should be treated the same as other infectious diseases. Why not treat them as smallpox is treated? In San Francisco patients with small-pox are either quarantined in the house or sent to the hospital; they are immediately isolated and compelled to be under observation; exactly as they are doing with venereal diseases, as far as possible. True, they cannot control them entirely, but if we, as physicians, or people, as business men, found that expenses could be decreased 10 per cent., would the opportunity not be embraced? If we could reduce a typhoid epidemic 10 to 15 per cent., we would think we were doing a good deal. Exactly the same with this: if you can control a small part of it, you have done something. If this clinic does no more than save one or two a month from developing syphilis it is accomplishing a good work.

Dr. Frances M. Greene, Cambridge, Mass.: When I first went to the laboratory of our great master, Rudolf Virchow, I was going to do more than anybody else ever did. I began at the beginning and worked for several weeks with might and main. Then the Geheimrath came to me and said: "Now, my child, when you begin to do a scientific work, the first thing for you to do is to find out what was done before, and if it was done, and well done, by reputable scientists; begin where they left off, but do not waste your time in doing the things that have already been well done." That is exactly what is being done in San Francisco to-day. It is a great paradox. Directly following the passing of one of the sanest laws—we are the one race that has had the courage to put these diseases where they belong, with other infectious diseases—we go back 100 years and begin where Napoleon began in France—trying to segregate the prostitute and control venereal disease in that way. Dr. Nevins, an English authority, calls attention to the fact that venereal disease of all kinds throughout the whole home Army, and also primary disease in the Army stations under *réglementation* (that is, under the contagious disease acts) show the same results—a large reduction of disease for six years before *réglementation*, under the influence of sanitary, social and moral agencies with the object of raising the character of the men. These agencies were still sporadic when *réglementation* was tried; and the disease still continued to fall, but at a low proportionate rate. The government, dissatisfied with comparative failure, stopped the pay of the men, sent them to the hospital for primary diseases, and the men ceased to report to the Army doctors. Hence the published statistics of the disease were unreliable owing to the amendment.

---

* The paper by Dr. G. L. Eaton, San Francisco, describing the attempts at regulation carried on in that city, is not yet published. The entire discussion is given here, however, following the remainder of the symposium.

It is a well-known fact that there are constant oscillations in this matter of venereal disease in all countries, whether they are under *réglementation* or not. In 1883 *réglementation* was suspended; that is, the theoretical examination of the women at a certain time when the soldiers were returning from Egypt, bringing a great deal of disease, and the figures rose for those two years. In 1886 parliament absolutely abolished *réglementation*, and venereal disease began to fall largely and steadily from 275 per thousand to 140 per thousand during the twelve years of abolition. In India there was a steady fall for seven years before regulation. After the introduction it went on falling, and then it rose again for nine years, at the end of which time, as in the beginning, it rose steadily; and at the end of twenty-one years it was twice as high as in the beginning.

Denmark had regulation eighteen years—1874 to 1891. During the first six years the army at Copenhagen showed sixteen cases to a thousand; during the last six years it showed 201 per thousand under regulation. The Dutch East India army under regulation showed 443 per thousand; the English in India at the same time, without regulation, showed 425 per thousand.

Now, it is an absolute fact, declared by every known specialist on venereal disease, that you cannot always diagnose a gonococcus infection, and that you cannot possibly control women by examining them, for this reason: these diseases may be passed by the vagina, even if the woman has no disease whatever. Here are the statistics in the British camp at Aldershot: In 15,000 men, among whom there was general inspection, Mr. Lawson found twenty-three per thousand in one regiment; 142 in another; and all of them under exactly the same regulation. In the English army, therefore, in order to investigate this matter, fourteen stations were selected and fourteen left without *réglementation* as an experiment; the lowest in the whole twenty-eight was in a camp in which there was no regulation. The same occurred in Holland and in Denmark. Pearson of Holland says that in certain cases women absolutely without disease would pass it on from man to man. At Hardwicke, in Holland, the women of the two houses of prostitution were rarely seen, but the numbers were enormous that had venereal disease, which went up to eighty-seven per thousand. In the Franco-Prussian war, at one place there were 200 women who were thoroughly examined, as they thought, but the hospital was filled with soldiers with venereal disease. They examined these women and found only one or two cases of disease in the whole 200.

The greatest of all specialists on this question, M. Fournier of Paris, says: "We cannot do *réglementation* well. It is impossible." They have had a commission there for years trying to better the conditions, but he shrugs his shoulders, as a Frenchman would, and says: "*Réglementation* may do a little good; but we have no right to do that little good, because we are doing a great deal more harm than that little does good."

What do you suppose it means in San Francisco to let our youth know that prostitutes are being inspected? These young, sincere and enthusiastic physicians who are trying to do it present their first statistics and declare that they have the diseases under control. What does it mean? That they say to the young boys in San Francisco: "It's all right, boys. Go ahead!"

In Berlin there are 5,000 prostitutes under absolute control. Do we hope, could we hope, in San Francisco, under a mayor who declares absolutely that the town is "open," who has opened every dive that a former good administration closed; who will not allow any measures to be used against dance halls—can we hope to make that police sufficiently conscientious to drag those women to the courts; and, after all, have we any right to drag those women? None whatever. None, more than we have to drag the men. But we can interpret the wise law which the State Board of Health has formulated. We may not get every case; but we must make every one, the prostitute as well as the non-prostitute, the men as well as the women, amenable to the law.

In Norway there is no objection to clinics; they have three; and while there are 5,000 legalized prostitutes there, they treat some 20,000 to 30,000 women every year, and men as well; and it is only in this absolutely just and sane way of treating the matter that we can hope to make any real progress. We must not assume from little sporadic indications that we have done it all; the thing that has existed for so many decades cannot be cured in three months!

Dr. W. F. Snow, Sacramento: We have in California a number of very interesting plans which are being tried out in the way of control of syphilis and gonococcus infections. Los Angeles is at one extreme of the problem and San Francisco at the other, with the State Board of Health trying to begin somewhere in the middle. Education of the people is the only thing which is going to help us permanently make progress on this problem, and I believe that the control of marriage is more important than the control of prostitution. The accurate reporting of syphilis and gonococcus infections cannot be overestimated. In California we now have a state law requiring syphilis and gonococcus infections to be reported. I supposed that it would be rather slow work getting reports from physicians, but it is not so. They are beginning voluntarily to report before our board has even had time to draft an explanatory letter stating what we wish on this subject.

We should make these diseases reportable by law in every state and city. I think we can do it without in any way involving the professional confidence between physicians and their patients; and I believe we can build on that, as Detroit has done, in an administrative way. I think, secondly, we should work for better laws controlling marriage and prostitution; thirdly, we should unquestionably come out in the open, as men and women, and discuss these things on a high and practical basis, and educate every boy and and (I want specially to emphasize this) every girl, with reference to the physiology and the hygiene of sex.

Here in California, as I said yesterday, over 85 per cent. of our children leave the schools when they are 15 years of age. Who helps them with this problem? Their parents do not. Their parents have not been taught how to help them wisely; our schools give them practically no instruction on this subject. Who helps them in that period of awakening passions, from the age of 15 to 27, when our young men in this state and the United States as a whole marry? Who tells them of the dangers of visiting the "red-light" districts? No one. I think we, as citizens of the United States, owe it to these young people from the age of 15 to 27 that they should know about the dangers of these communicable diseases, the facts of sex hygiene and physiology, and the sacredness of marriage, that in their time they may come to realize that greatest of all human blessings, a happy home and family.

Dr. E. Stuver, Fort Collins, Colo.: We have done a great deal in the last few years in the attempt to stamp out tuberculosis and to educate the people as to the dangers following from this disease. I believe that venereal diseases to-day are causing a great deal more trouble, sorrow and death in this world than is tuberculosis; and I believe that we should devote as much or more time to the stamping out of these diseases as we devote to that of tuberculosis.

I fully believe that every case of venereal disease should be reported. About sixteen years ago I read a paper before the Colorado Medical Society advocating the reporting of these diseases and the isolation of those affected with them in special hospitals for that purpose. To me, the most important thing in connection with the prevention and control of venereal diseases is education. I believe that we, in the reading of papers, speaking in discussions, and all that sort of thing, at our meetings, should do that; and not only that, but we should go back home to our several communities and constitute ourselves a committee of one and carry this expression to the people who are under our charge. I believe that every physician here, by approaching the director of the Y. M. C. A., the superintendent of the schools, or in other ways, could have the privilege of educating the people of his community.

During the last couple of years I have delivered a course of lectures to the boys of our Y. M. C. A. on this very subject. I have also given a couple of lectures to the nurses in our training school on the subject, because no one is more exposed to the dangers of venereal infection than the nurse. By this individual, enthusiastic work on the part of every physician in the country we could soon so arouse the people that they would say that venereal diseases must be controlled. I do not say stamped out, because I do not believe, as long as human nature is constituted as it is, that we will be able to stamp out venereal disease; but I do believe that we can place it under such control that the innocent will be protected and there will be no necessity for anybody being ignorant on the subject. And, as before stated, nearly all the young boys and girls at the present time are really ignorant on this exceedingly important subject.

Dr. S. A. Knopf, New York: The control of syphilis and venereal diseases in general, as has been outlined by the preceding speakers, I most highly approve of. There is, however, one phase which should not be forgotten. That is to say, every city should do as New York has done—have an open house for the girl who wishes to leave that life. We have in New York such a house; we call it simply Waverley House, not Magdalene Home. We do not like that name. We let every girl who voluntarily wishes to return to a proper life enter there; no questions are asked. Most of our judges, when about to sentence a girl who has come up for the first or even a second time for soliciting, give her a chance to go to this probation or Waverley House and be under the care of a probation officer. Last year no less than one-third of all the girls received at that home returned to society as honest members. They have left their life of sorrow and shame voluntarily; they have returned to their parents, have been given positions, or have been provided a trade, so that they can now earn an honest living. The society providing this home for the unfortunate girl is incorporated under the laws of the State of New York, and the best men and women of the community are interested in its work and help to maintain it.

Therapeutics

ASPHYXIA

By asphyxia is commonly understood "a state of suspended animation caused by impeded respiration, as by strangulation, smothering, submersion, or the inhalation of an irrespirable gas" ("Foster's Medical Dictionary"). To these conditions should be added asphyxia due to electric shock or lightning stroke.

Asphyxia is one of the grave surgical emergencies which demands instant action by anyone present who knows what to do. Every physician should be conversant with the best methods to employ in treating patients in this condition. Its importance is equaled only by another grave surgical emergency, that of hemorrhage from a large vessel.

The forms of asphyxia which we are most likely to encounter are that of the new-born, that which is present in drowning, that which occasionally occurs during the administration of an anesthetic, and that due to the effect of electricity or lightning.

ASPHYXIA NEONATORUM

This condition is one which every obstetrician should be prepared to treat promptly. In milder degrees it occurs in a large proportion of deliveries. In its more severe forms it fortunately is less common.

The more common causes of the condition are premature detachment of the placenta, prolapse of the umbilical cord, excessive use of chloroform, of chloral, or of morphin administered to the mother to diminish the pain of labor, or large doses of ergot given during the second stage of labor to increase the contraction of the uterus, extreme compression of the head of the child owing to unusually severe contractions of the uterus separated by brief intervals, obstruction to the passage of the head by narrowness of the pelvis, compression of the head by unskilful delivery with forceps, compression of the after-coming head in the delivery of breech cases, and compression of the cord through its being wound around the child's neck, or through its being drawn into a knot.

The preventive treatment naturally is based on a consideration of these causes. In instrumental delivery great pressure on the head of the child should be avoided, and the traction should be made intermittent and not continuous. If there is prolapse of the umbilical cord, it should be replaced, the woman placed in the knee-chest position, and every effort made to retain it until the head has become engaged at the brim of the pelvis. In all severe labors preparation should be made before the birth of the child to apply suitable treatment in case it should be born in a condition of asphyxia. These preparations should include a baby's bath tub with a supply of warm water conveniently at hand, a bowl of cold water, a warm woolen blanket, small pieces of gauze, a bottle of aromatic spirits of ammonia, a bottle of whiskey and a hypodermic syringe.

As soon as the child is born it should be promptly slapped repeatedly on the buttocks and back. The mouth and throat should be wiped out with a piece of gauze so as to clear out any blood, mucus or amniotic fluid which may be there. If this does not promote the reflex action of breathing, the cord should be felt to see if it is pulsating.

By this time one has had an opportunity to inspect the surface of the child to see whether the condition is one of *asphyxia livida*, in which the skin is congested and livid and the reflexes are maintained; or whether the condition present is *asphyxia pallida*, in which the surface is pale and cold, the muscles are relaxed, and the reflexes are absent. The treatment should vary somewhat according to which of these two conditions is present.

If the condition is one of *asphyxia livida*, with congestion of the skin, there is some difference of opinion as to whether the cord, if it is pulsating, should be at once cut and a small amount of blood allowed to escape, or whether it should not be cut until later. Probably it is wiser to postpone this for five or ten minutes. In the meantime the child should be grasped by its feet in the left hand of the physician and held in an inverted position while several light blows are administered on the buttocks, shoulders and chest, in order, if possible, to expel any more blood or mucus which may be in the larynx and trachea. This position should be maintained for only a few seconds.

Next, the Byrd Dewey method of artificial respiration should be tried. This consists in placing the palm and fingers of the right hand under the child's shoulders while the index finger and thumb support its head, the left hand being placed under the hips. With the child in this position, by raising the radial sides of the hands, the legs and knees of the child are brought up onto its chest and the chest is compressed so that the air is expelled; then reversing this position and allowing the head and shoulders to fall backward, the chest is expanded and the air drawn in. These maneuvers should be repeated at intervals of about five seconds, so that the procedure will be repeated from ten to fourteen times in a minute. If the cord is of average length, this can be done before the cord is cut.

If the cord has not been cut before, it should be now, and the child at once placed in a tub in which water of a temperature between 100 and 105 F. has been placed. This will promote the circulation in the skin and prevent the body from being chilled, and further treatment may be carried out.

The next method of encouraging respiration is that known as the method of Laborde. This consists in grasping the tip of the tongue either with the thumb and finger, with the aid of a piece of gauze, or with forceps, and drawing it forward and then letting it fall backward. This should be repeated from ten to fourteen times in a minute, and may be continued for one or two minutes. While this is being done the child should lie with the head drawn slightly backward, or on one side.

If the child does not breathe by this time, it is well to take it out of the warm water and plunge it into a bowl of cool water of a temperature of from 65 to 75 F. It should be allowed to remain there but a few seconds, and then placed back in the warm water. In the meantime it should be vigorously rubbed, but at the same time caution should be used not to rub it harshly for fear of doing serious damage to the skin.

In some cases it has been found that inserting the tip of the little finger into the anus will stimulate the reflex action of breathing.

Another method not infrequently employed is that known as the method of Schulze, which consists in standing back of the child, placing the palmar surfaces of the three outer fingers under its shoulders, the index finger of each hand under the axilla, and the thumbs on the chest, with the ball of the thumb resting on each side of the child's head. The physician thus grasping the child and then standing erect, gradually swings the child forward and upward in front of himself until it is above his head. In this position the child's thighs and legs fall against its chest, which is thereby compressed and the air forced out. Then swinging the child back into the original position, the chest is expanded, and the air enters. This may be repeated at intervals of five or six seconds, so that it will be done from ten to fourteen times in a minute. This is a method which presents more or less of the appearance of violence, and hence it is not always practicable to do it in the presence of the friends of the patient. It should also not be practiced if there are fractures of any of the bones, or if the child is especially feeble, or has been born prematurely.

If difficulty has been experienced in clearing the larynx and trachea of mucus, a small soft catheter may be inserted through the larynx into the trachea, and any mucus present drawn out, either by the physician himself or with the aid of a syringe or aspirator.

If other methods fail, it is recommended to blow air into the lungs of the child. This may be done by the so-called mouth-to-mouth method in which, a piece of gauze being placed over the mouth of the child, the physician filling his cheeks with air expels it into the mouth of the child, at the same time holding the child's nose. This method is somewhat inexact, as much of the air frequently goes into the stomach, but some of it goes into the lungs, if they are not already distended. After blowing air into the lungs, the chest should be compressed so as to drive it out again.

A few drops of ammonia on a piece of linen may be held under the child's nose, but not too closely, with the hope that this will stimulate respiration and, as it sometimes does, muscular contraction.

A hypodermic injection of 8 to 10 drops of whiskey is frequently recommended. Other things recommended are a hypodermic injection of a drop of tincture of belladonna or 1/1,000 of a grain of strychnin.

If by the time all these methods have been tried the child has not commenced to breathe, the physician naturally wonders how long he ought to continue his efforts. The answer to this question depends largely on the condition of the heart. He should continue efforts at artificial respiration and external stimulation as long as the heart beats. After it has been impossible for five minutes to detect any pulsation of the heart, it is useless to continue any further efforts at resuscitation.

If the efforts have been successful and the child commences to breathe, even if the breaths are taken at long intervals, one should avoid an over-anxiety in interfering with the natural performance of the function by the child. Once it has begun to breathe it probably will continue to breathe and the breaths will increase in depth and frequency until they become normal.

Turning now to the other class of asphyxia neonatorum, viz., *asphyxia pallida,* in which the reflexes are absent and the heart is weak; if the cord is not pulsating, it should be immediately cut and the child placed in a tub of warm water. If, however, it is pulsating the child should not be separated from the mother until the pulsation has ceased. The same methods are applicable in these cases as in the others, except that the more violent ones had better be omitted and all the efforts concentrated on the employment of the milder methods, especially the rhythmical traction of the tongue as practiced by Laborde. Especially is it important to maintain the temperature of the child, and the water in the warm bath should be maintained at a temperature of 100 or a little higher by adding fresh warm water as fast as the water in the tub becomes cool.

After the child has gained the ability to breathe regularly it should be carefully watched for several days, for if there has been difficulty in relieving the asphyxia, there is danger that it will become feeble and die in the course of a few days. It should be well wrapped up, and the external heat should be maintained. Whiskey may be given in doses of from 3 to 5 drops every two hours. The milk should be drawn from the mother's breast and fed to it with a medicine dropper, if it is not able to take hold of the breast and draw for itself.

(To be continued)

Martyrs of Science.—Unhappily every important new development in human knowledge brings its martyrs. When Langerhans, in 1896, lost his 2-year-old son—the first definitely recorded death following the use of serum—ignorance and wilful prejudice sought to attribute it to antitoxin. No one was yet sufficiently alert to see the great significance to humanity of the phenomenon that most likely was the cause of this pitiful sacrifice.—R. G. Eccles in *Medical Record.*

SATURDAY, SEPTEMBER 23, 1911

THE ACTION OF TROPICAL SUNLIGHT

Modern investigation of tropical diseases has been so successful that in our enthusiasm we are apt to consider these as the only influences deleterious to life in warmer climates. It must be remembered, however, that the physical peculiarities of the tropics also have their effect on the animal economy—an effect the exact importance of which it is difficult to estimate. These various physical factors of a tropical climate are being studied, and Aron[1] in recent articles gives the results of his investigations on the effect of tropical sunlight on the living organism.

It is obvious that sunlight in equatorial and subequatorial regions will be more potent than that of more temperate zones; for not only does the perpendicular course of the rays make the intervening protective layer of the atmosphere relatively thinner, but it also results in a greater intensity of illumination for any exposed area. The actual occurrence of this greater power is readily shown by measurement of the chemical activity of tropical sunlight as compared with that of colder latitudes; and, possibly as a result of such experiments, the idea has been prevalent that the harmful effect of sunlight is primarily due to the chemically active (actinic) rays. It was because of this idea that orange-colored underwear was tried on soldiers in the Philippines—an experiment that, as is well known, was unsuccessful. The other view, that it is the infra-red heat rays that are most powerful for harm, is held by Aron, and he advances experimental evidence in its support.

In the temperature regulation of a normal isothermic animal, two opposite tendencies are constantly closely balanced, heat production and absorption being neutralized by various devices for giving off heat. Should the production or absorption of heat reach a point beyond the compensating powers of the eliminating mechanism, or should this latter for any reason fail to act properly, heat is retained in the body, and a rise of temperature follows. Thus, if a dead animal, in which the heat dissipating devices are of course inactive, be hung in the warm sunlight, its superficial temperature will rise rapidly, and its deep, rectal temperature will rise also, but more slowly. A living animal, on the other hand, while absorbing heat at the same rate, will avoid its retention by increased elimination, with the result that the surface rise will be unaccompanied by the increase of deep-temperature. So, for instance, a dog in these circumstances may attain a surface temperature of over 104 F., while the rectal temperature will not have risen beyond 101 or 102. But its rapid respiration and lolling tongue will give evidence of the means taken to attain this result. If the dog be tracheotomized, so as to cut off this method of heat dissipation, rectal and subcutaneous temperature will both rise, and the animal will rapidly succumb. The magnitude of the heat elimination by vaporization of body secretions may be judged by the fact that rabbits in the sunlight were found to lose in this way from six to seven times as much weight as their sheltered fellows.

The most interesting results were obtained with apes. In these, the superficial temperature is normally ½ to 1 degree lower than the deep temperature, but on exposure, if only for a few minutes, to sunlight, this relation became reversed; if exposed long enough to cause death —which takes only a short time for these animals—the superficial temperature exceeded the deep by one-half a degree. Shaving the animals emphasized these differences, and shortened the fatal period markedly. If a current of air was kept in circulation over the exposed animal, however, it became capable of resisting the action of the sunlight indefinitely. Conclusive evidence against the supposed direct action of the actinic rays on the meninges was afforded by a simple experiment. An ape was encased in a double-wall box in such a way as to expose its head only to sunlight. Absolutely no harm resulted to the animal, although a superficial scalp temperature of 116.5 F. was attained.

The effect of sunlight on human beings was also studied. The normal human superficial temperature was found to range from 90 to 92 degrees F., but on exposure to sunlight this rose rapidly to 96 and 97 degrees. Farther exposure resulted not in farther rise, but in an actual drop of one-half or one degree, coinciding more or less closely with the appearance of perspiration. With muscular exertion, this fall was both greater and more rapid. In general, colored individuals did not attain as high superficial temperatures as did the whites, although from the greater absorptive powers of pigmented skin the reverse would be expected. This Aron believes to be due to the earlier onset of perspiration, possibly occasioned in part by the greater heat absorption. Visible perspiration, however, is less marked in colored than in white races, but as he points out, it is the invisible, vaporized perspiration that is effective in temperature reduction, and there is a distinct possibility of "economy of sweat" in races habitually requiring its protective influence. Aside from this, colored individuals have an advantage in their ability to go uncovered without danger of the painful solar dermatitis to which whites are so subject.

---

[1] Berl. klin. Wchnschr., 1911, xlviii, 1115; Philippine Journal of Science, April, 1911.

The chief importance of Aron's work lies in its overthrow of the "actinic theory" of solar action. It is obvious that this more correct knowledge of the effect of the sun's rays makes possible the adoption of rational means of protection against them, and so affords an additional step toward increasing the habitability of the tropics for races of northern origin.

ORGANIC MATTER IN EXPIRED AIR

Most of us are aware by experience of the acute discomfort that may be caused by continued reinspiration of expired air. And the assurance of experimenters in this field that this is mainly the result of the unduly high temperature and moisture content of the air has scarcely seemed adequate to explain a phenomenon so pronounced. Indeed, aside from the testimony of everyday experience, the evidence as to the toxicity of impure air is itself of a most contradictory character. Thus, while Hammond, Brown-Séquard and d'Arsonval, and Davis secured results pointing unmistakably toward such toxic action, a considerable number of other observers, some of them duplicating the methods of Brown-Séquard and his fellow workers, have come to the opposite conclusion. It has been shown with practical certainty that air expired during normal quiet respiration is almost wholly free from microorganisms, so that in the absence of droplet infection any immediately harmful effects of impure air can scarcely be ascribed to bacterial contamination; and with the failure to demonstrate other impurities, the assumption that it is entirely the moisture and temperature of expired air that produce discomfort, has reached wide-spread acceptation.

In view of this conclusion, much interest attaches to recent work by Rosenau and Amoss,[1] in which they have apparently found in used air, by means of the anaphylactic reaction, minute quantities of organic matter. Their method was to collect the condensed vapors from human breath, to inject these into guinea-pigs, and after a suitable interval, to reinject these animals with small quantities of human serum. In all, ninety-nine animals were so tested in twenty-five different experiments, and of these twenty-six gave definite evidence of an anaphylactic reaction. The experiments were carefully controlled bacteriologically. Unfortunately no description of the methods followed in collecting the air, beyond diagrams of the apparatus used, is given, and there is a possible doubt as to the freedom of the condensed vapors from contamination with material mechanically carried over. It is true that as a control on this possibility, a number of guinea-pigs were tested similarly with human saliva, with negative results; but it is difficult to understand why saliva, which would apparently be saturated with air and whatever impurities might be in the air, should fail to give the same reaction as the condensed vapors.

While it would seem that further work might be desirable to establish beyond doubt the presence of organic matter in expired air, it is evident that the results just presented, if so confirmed, will be of marked interest and value. For although no evidence has been adduced as to the toxic character of the organic matter, the mere demonstration of its presence is a marked advance on our present knowledge of the action of impure air. It would seem also, as Rosenau and Amoss point out, to clear up the problem of the anaphylactic reaction sometimes observed after the first injection of foreign serum, particularly diphtheria antitoxin. And finally, it would serve as an instance of a phenomenon hitherto wholly unsuspected—the volatilization, or gaseous solution, of a substance of the complex composition and high molecular weight of the proteins.

THE CHARGE AGAINST DR. WILEY

III.—THE DENVER MEETING

While the decision of the President disposes of the charges and completely vindicates Dr. Wiley, the evidence presented before the congressional committee is so interesting and illuminating on other subjects that we continue to present to our readers extracts from this testimony.

This week, these extracts relate to the meeting of the Association of State and National Food and Dairy Departments in Denver, in 1909. At the previous meeting, at Mackinac Island, in 1908, resolutions had been adopted deploring the failure of the Secretary of Agriculture to cooperate with the state food departments in the development of uniform standards and the enforcement of pure food laws. At the same meeting, the retiring president, Prof. E. F. Ladd of North Dakota, in his presidential address, referred to the Remsen board as a "specially constituted board of doubtful constitutionality," standing between Dr. Wiley and "the interests." He emphasized the need of uniform standards for the proper enforcement of state and national food laws and deplored the lack of cooperation between the state authorities and the Department of Agriculture. Furthermore, a few weeks before the Denver meeting, the American Medical Association had adopted resolutions urging Congress to amend the Food and Drugs Act so as to prohibit the use of benzoate of soda as a preservative.

The Denver meeting was selected by the reactionaries and the manufacturers of adulterated food products as an opportunity to counteract the rapidly growing sentiment against the use of preservatives in foods. The testimony shows, what has long been popular knowledge, that every effort was made by the Secretary and by many employees of the Department of Agriculture to control the meeting. It should have been a dignified gathering of representative scientific men, deliberating on ways and means of enforcing the pure food laws for the protection of the people. It degenerated into a semipolitical

---

[1] Jour. of Med. Res., 1911, xxv, 35.

Donnybrook fair, in which any means were used to secure and to retain votes. Solicitor McCabe's testimony shows that he was not only present at the head of the delegation from the Department of Agriculture, but that, several weeks before the meeting, he went West to round up as many votes as possible to back up the referee board and to discredit Dr. Wiley. McCabe says, "I interviewed every man I met that would probably come to the convention and I asked every man of that kind I met to uphold the department when he got there." The Remsen board, which had been conveniently sent to California, stopped at Denver on the way East, and so was present at the meeting. Professor Remsen says that the board was "requested," and not "directed," to attend the Denver meeting, but Secretary Wilson's formal letter of Aug. 6, 1909, sounds strangely like an order. Professor Remsen says in his letter of June 30, 1909, that the board is "anxious . . . to get things on a solid, scientific, common-sense basis." This was a highly commendable attitude on the part of the Referee Board, but if the question was to be settled on a scientific basis, where was the necessity of McCabe's electioneering activities? When have scientific men settled doubtful questions by popular vote and by political methods rather than by carefully considered evidence?

It also seemed odd at the time, and even at this late day it reads strangely, that, in spite of the presence at this meeting of scientific men, of the Secretary of Agriculture, a member of the official family of the President of the United States, of the entire Referee Board, of several employees of the Department of Agriculture, to say nothing of swarms of lobbyists and agents of borax companies and catsup manufacturers—in spite of all this assistance for the establishment of a scientific truth, benzoate of soda was "vindicated" by the vote of nineteen states to fourteen states, with three not voting. Rather a barren victory for a "scientific proposition."

The Denver meeting has passed into history. Some of those who attended this meeting and participated in its deliberations doubtless thought, when the meeting adjourned, that the benzoate question was settled and would return no more to annoy them. But, alas, two years later, all the details of this meeting and of the "scientific" way in which this question was settled, are brought out before a congressional committee. Nor is this all. Unless the leaders of the Democratic majority in the Lower House are blind to a great opportunity to act for the public good, next winter will see the same question again ventilated on the floor of Congress. *Hæc fabula docet* that a question is never settled until it is settled right.

IV.—THE CASE OF DR. ROBISON

Probably the most incredible single act disclosed by the hearing before the congressional committee was the treatment of Dr. Robison of Michigan by the Secretary of Agriculture. Dr. Robison, formerly State Chemist for Michigan, was duly appointed on a per-diem basis as a civil-service employee of the United States Department of Agriculture in 1907. In other words, he was not permanently employed, but worked when called on and was paid for the time he worked. In 1909, he went to the Denver meeting of the Association of State and National Food and Dairy Departments as one of the representatives of his state. He received no pay from the Department of Agriculture for his expenses. He was not, at that time, drawing any salary from the federal government. He attended as a scientific man, representing a state government, and presumably free to hold any opinion on any question which might come before the meeting. He was appointed by the president of the Association of State and National Food and Dairy Departments as the chairman of a committee of eleven state food chemists to prepare a report on benzoate of soda. On this committee he represented the state of Michigan and not the Department of Agriculture. This committee prepared a report which "respectfully suggests to the President of the United States and the honorable Secretary of Agriculture to institute investigations along some such broader lines as indicated above." This is one of the offenses for which Dr. Robison was summarily discharged.

Dr. Robison's second offense was that he did not vote for the candidate for president of the association favored by Secretary Wilson. On this point, Dr. Robison says (letter to Secretary Wilson, Aug. 4, 1911): "My own state had a candidate for the same position, and inasmuch as I did not represent your department or draw either salary or expenses from it, I felt it my duty to support the candidate from my own state."

The third and apparently the most serious offense: Dr. Robison was summoned as a witness in the Indiana case. He was not at this time drawing a salary from the United States government. His expenses were paid by the Indiana State Board of Health. He was paid nothing for his time. He says, "I testified according to the truth, as I understood it to be and had found it from my own investigations and according to my oath, and without any regard in any capacity to any other policy." Secretary Wilson said: "You appeared . . . in opposition to the policies of the administration with regard to the reports of the Referee Board on benzoate of soda and the report of the three secretaries with regard to it."

Secretary Wilson, explaining his summary discharge of Dr. Robison, said: "I do not propose to have subordinates in my department going off on tangents that are against the decisions of the three secretaries and myself, and all that, after we have gone to the expense of hiring such noted experts and scientists as we did to make up that Referee Board. I propose that gentlemen will work in line or keep still about it."

In such ways and by such methods, has the Department of Agriculture sought to enforce its opinions regarding benzoate of soda. We reproduce (pages 1071-1072) practically all of Dr. Robison's testimony since we believe it will prove instructive and interesting.

Current Comment

DR. WILEY EXONERATED

President Taft has exonerated Dr. Wiley of the charge preferred against him. In doing so, he has given official voice to the verdict already rendered by the American press and people. If the attack against Dr. Wiley were a mere personal fight, The Journal could allow the matter to rest here; but it was a principle, not a man, that was at stake. Dr. Wiley's enemies are opposed to him because he represents a principle—that of protection to the consumer. They would be equally antagonistic to any other individual holding the same position and actuated by the same ideas. For this reason we continue to publish the testimony that was given before the congressional committee. The evidence that was given there is of value because, for an all-too-brief space, the curtain was partly drawn aside and the pernicious activity of those interests that are arrayed against the public health was disclosed. Of the venomous and harassing tactics of McCabe and the sycophantic attitude of Dunlap in the carefully laid plot to depose Dr. Wiley, the President says nothing—at present. He does indeed hint that the demoralized condition of the Department of Agriculture will call for executive action: "The broader issues raised by the investigation, which form a much weightier relation than this one to the general efficiency of the department, may require much more radical action than the question I have considered and decided." If by these words President Taft means that he will, at the earliest convenient opportunity, sever the connection of McCabe and Dunlap with the government, he will find that he is merely expressing the opinion of the American people as to what should be done in this matter. Meanwhile, congratulations are due to the President on the wisdom of his decision, to Dr. Wiley, on being exonerated from the malicious and unfounded charge, and to the people of the United States, because they still have Dr. Wiley to stand between them and the food adulterators.

ALBRECHT KOSSEL

The series of lectures which is supported at Johns Hopkins by the endowment of the late Dr. Christian Herter, will this year be given by Prof. Albrecht Kossel, professor of physiologic chemistry at the University of Heidelberg. In 1910 Professor Kossel was awarded the Nobel prize in medicine in recognition of his researches on the composition of the constituents of the nuclei of cells, especially on the nucleins and their components, a summary of which is given in his address on "Die chemische Beschaffenheit des Zellkerns,"[1] delivered at the time of the award of this prize. Kossel's studies are of fundamental importance in biologic chemistry, and the award of the highest honor in medicine was richly deserved and universally approved, although as yet the results of his work have not found direct application in the practice of medicine. He had already made extensive and productive investigations into the composition of the proteins at the time when Emil Fischer, turning aside from his triumphs in the chemistry of the purins and of the carbohydrates, introduced new methods for the isolation of the constituents of the protein molecule and with swift strides dominated this field. While Fischer's work added especially to our knowledge of the mono-amino-acids of proteins, Kossel placed on a firm footing the study of the diamino-acids, which occur in especially large proportions in the nuclear proteins of germinating cells. The simplest proteins known, the protamins, consist chiefly of the diamino-acids, and so prominent and constant a part of all proteins is formed by one of these diamino-acids, arginin, that Kossel advanced the hypothesis of an arginin nucleus for all protein molecules. With his students Kossel has also made extensive investigations on the non-protein elements of nuclear material, namely, the purins, the pyrimidins and the carbohydrate radicals. To the many American students in Heidelberg Professor Kossel is known as a most interesting and lucid lecturer on a difficult topic, and he will find in America many old pupils not only in the science faculties, but also among practicing physicians.

SECTARIAN LICENSING BOARDS—AN OBJECT-LESSON IN PENNSYLVANIA

It has been repeatedly asserted that higher standards of medical licensure will not be uniformly effective so long as the enforcement of such standards depends on different boards representing and favoring different medical sects. That such an arrangement provides makeshifts whereby unfit candidates are enabled to secure licenses has long been known; Pennsylvania has demonstrated this very effectually. In that state responsibility for the enforcement of the medical practice act was parceled out to three separate boards, regular, homeopathic and eclectic. As may be noted in the report of the last examination, published this week,[1] out of forty-one candidates examined by the eclectic board only seven were graduates of eclectic colleges and two held diplomas from a nondescript institution, while thirty-two, or 78 per cent., were graduates of so-called regular medical colleges! Of these thirty-two, it also should be noted, twenty-five were graduates of a single medical school, rated in Class C by the Council on Medical Education — the Maryland Medical College of Baltimore. Further, official reports show that during the last three and a half years only seventeen graduates of eclectic colleges have been examined by the Eclectic Board of Pennsylvania and every one of these seventeen passed and received a license to practice medicine; during the same period, however, this eclectic board examined 117 graduates of regular and homeopathic colleges. Incidentally, as might be expected, these 117 came chiefly from notoriously low-grade institutions — and only seven failed! Happily, however, Pennsylvania has adopted a new medical practice act, providing for a single board of medical examiners, which will become effective the first of next year. If this practice act is properly enforced it will put a stop to such makeshifts in the licensing of physicians as have been reported from Pennsylvania for several years past. In this day of scientific medicine, there is no excuse for laws which place the responsibility for their enforcement in the hands of from two to four special and avowedly prejudiced boards. The people of Pennsylvania are certainly to be congratulated on the change soon to take place in their state, a change which comes none too soon.

Medical News

ILLINOIS

Personal.—Dr. Sidney D. Wilgus, superintendent of the Elgin State Hospital, has been appointed superintendent of the Kankakee State Hospital, vice Dr. Frank P. Norbury, appointed a member of the State Board of Administration to succeed Dr. James L. Greene, Springfield, resigned, to take charge of the Arkansas State Hospital, Little Rock.——Dr. Emerson M. Brewer, Rantoul, local surgeon, has been promoted to district surgeon for the Illinois Central system.——Dr. L. M. Griffin has been appointed local surgeon at Polo for the Illinois Central system.——Dr. Wallace Blanchard, Chicago, has returned from Europe.

INDIANA

State Society to Have Banquet.—For the first time in twenty-two years the Indiana Medical Association will have a banquet at its annual meeting which is to be held in Indianapolis, September 28 and 29. On the days preceding and following the meeting, clinics will be held at the city hospital.

New City Hospital.—A committee of physicians of Indianapolis, consisting of Drs. Samuel E. Earp, J. Rilus Eastman and James H. Ford, appointed by the board of public works, have prepared specifications for a new city hospital, with accommodation for 500 patients. The plans follow closely those of the Harvard Hospital.

Personal.—Dr. A. P. Schier, Evansville, has been appointed first assistant physician in the Indiana Southern Hospital for the Insane, vice Dr. John F. Glover, resigned.——Dr. John Medaris, Brookston, who has been seriously ill is reported to be improving.——Dr. John W. Ballard, Logansport, had a slight cerebral hemorrhage in his office, September 9.

Rules Regarding Communicable Diseases.—The Indianapolis Board of Health has adopted the following rules for medical inspectors in the city schools: Any child having a communicable disease shall be excluded from the school; all children of a household where there is diphtheria, scarlet fever or small-pox shall be excluded from school; all children of a household where there is whooping-cough, chicken-pox or mumps may attend school except the child having the disease; all children of a household where there is measles may attend school except the child having the disease and the child who has not had the disease. Six physicians have been added to the staff, making now a total force of twenty-six inspectors of public schools.

KENTUCKY

Money for Health Exhibit.—Dr. W. E. Grant, health officer of Louisville, will make application to the city for an appropriation of $3,000 for Louisville share toward the erection of a permanent building on the Kentucky State Fair Grounds for health exhibit. The State Board of Agriculture will, it is thought, also appropriate $3,000 toward the project.

Personal.—Dr. Louise B. Triggs, Lakeland, has been appointed physician to the female department of the Hopkinsville State Hospital.——Dr. Herbert Bronner, Louisville, was attacked in his office by an insane patient armed with a revolver, but fortunately escaped injury.——Dr. Nathan R. Simmons, health officer, Lexington, is ill at his home with rheumatism.

State Board Meeting.—*At the meeting* of the Kentucky State Board of Health held in Louisville, September 13, Dr. John G. South, Frankfort, was elected president. Dr. Joseph M. Mathews, Louisville, in nominating Dr. South stated that since the organization of the board the office of president had been held by older men, and he was in favor of recognizing the younger members of the board. Dr. William A. Quinn, Henderson, and Dr. Joseph M. Mathews, recent appointees, were sworn in as members of the board. Dr. Mathews' term had expired, and Dr. Quinn had forfeited his membership by being elected a member of the Henderson Board of Education, but on his resignation from this board, was reappointed a member of the State Board of Health.

LOUISIANA

Free Medicine Commission.—The mayor has appointed the following commission to administer the Sickles fund for the free distribution of medicine: Drs. Sara T. Mayo, William T. O'Reilly, Joseph A. Danna and Marion Souchon, Rev. J. C. Barr and Messrs. E. H. Singreen and A. B. Tippin. The fund now aggregates about $108,000, of which only the interest, which amounts to about $5,000 a year, can be used.

Brief of Work of State Board.—During the last fiscal year the work performed by the State Board of Health includes the tour of the health exhibit train through Louisiana and several other states, in the interest of sanitation and hygiene; the abolition of the public drinking-cup and towel; the appointment of commercial travelers as subsidiary inspectors; the regulation of barber shops; the adoption of model vital statistics; the registration of dairies; formulation of the *plan for distribution of antidiptheria serum for the poor*, and the adoption of a report covering the work of a year made on the condition of the waters of Bayou Teche.

MARYLAND

Baltimore

Herter Lectures.—The sixth course of lectures on the Herter foundation will be given October 4, 5 and 6, in the auditorium of the physiologic building of Johns Hopkins University, by Dr. Albrecht Kossel, professor of physiology, and director of the physiologic institute of the University of Heidelberg. The subjects of the lectures will be "Proteins" and "Metabolism." The lectures will be given at 4 o'clock, and physicians and students are cordially invited to attend.

Personal.—Dr. Harry Friedenwald arrived home from Palestine, September 12, and says that he does not intend to make his future home in Asia, but expects to remain in Baltimore.——Drs. Mary Sherwood and Lillian Welsh are attending the International Congress for the Study and Prevention of Infant Mortality, in Berlin.——Dr. Thomas R. Brown sailed for Europe, August 24.——Dr. F. Oehlecker, Hamburg, who is making a study of hospitals in the United States, visited Baltimore, September 8.

MINNESOTA

Personal.—Dr. Webber, Leech Lake, has been made physician at the San Juan Indian Agency, Shiprock, N. Mex., vice Dr. Lewis C. Day, transferred.——Dr. E. H. Bailey, St. Paul, has been appointed superintendent of the Wabasha County tuberculosis sanatorium.——Dr. John S. Holbrook has been reelected president, and Dr. William A. Beach treasurer of the board of education of Mankato.

MISSOURI

New Building at Sanatorium.—A new building has been completed at the State Sanatorium for Tuberculosis, Mt. Vernon, which will accommodate about seventy-five patients, thus doubling the capacity of the institution.

Personal.—Dr. James A. Waterman, Kansas City, formerly physician at the penitentiary, has been appointed superintendent of the Farmington State Hospital. Drs. William S. Hutton, Fornfelt, and John A. Tiller, Bloomfield, have been appointed assistant physicians at the same institution.

A Bnai Brith Sanitarium.—A canvass was commenced in St. Louis, September 15, to raise $75,000 as a building fund to erect a nonsectarian sanitarium at Hot Springs, Ark., under the auspices of Independent Order of Bnai Brith, a Jewish fraternal organization. The sanitarium will be for the benefit of dependent sufferers from rheumatism and blood diseases.

Medical Library Club Established.—A medical library is to be established in Kansas City, with rooms on the thirteenth floor of the Rialto Building. The greater number of the office rooms in the building will be occupied by physicians, and the owner has devoted the entire west wing on the thirteenth floor to space for the library, free of charge. The club now has sixty members, one of whom has promised to lend his own medical library. The membership is divided into three groups, and $2,000 has been already subscribed for the institution. The committee on organization consists of Drs. Edward H. Skinner, Arthur E. Hertzler, Jabez N. Jackson, Franklin E. Murphy, Harold P. Kuhn, William J. Frick, Richard L. Sutton, Howard Hill, Robert M. Schauffler and Herman E. Pearse.

St. Louis

College News.—Barnes University, according to an announcement made to the alumni at a banquet recently, is now free from debt. Dr. Charles H. Hughes renews his affiliation with the school and is president of the board of trustees.——Rumors of the absorption of the American Medical College and the College of Physicians and Surgeons have been revived.

Woman's Society for Pure Food.—A woman's movement has been started with the object of stamping out impure food products, following a meeting September 14 at which simple tests for detecting impure foodstuffs were demonstrated by Mr. Rhey McCord, manager of the pure food exhibit. Mrs. W. E. Fischel was elected chairman of the temporary organization, with instructions to submit plans for the permanent organization at a subsequent meeting.

Hospital Thief.—Several physicians have been robbed recently by a sneak thief who, declaring himself a country physician desirous of witnessing operations, would be given the freedom of the hospital and privilege of presence in the operating room. He then would leave the room before the operation was finished and pilfer money and valuables from the physicians' clothing. Physicians at the University, St. Anthony's and St. Mary's hospitals have been thus victimized.

Hospital Situation.—Mayor Kreismann has taken a hand in the hospital muddle and has promised that the hospital board shall receive $1,500 monthly additional for food for patients. The disclosures following an investigation by a committee of the House of Delegates aroused the people to a realization of the needs of the hospitals. The visiting staff system of treating patients has proved far superior to former methods. In addition to extra money for food, provision will be made at once for an adequate number of graduate nurses and for the instruction of student nurses at the City Hospital, and dietists will be employed at all institutions.

Upheaval Concerning Milk-Supply.—Newspapers, civic organizations and citizens have become agitated over the milk-supply owing to recent declarations by the State Food and Drug Commissioner that the milk-supply of St. Louis is the product of insanitary, ill-kept and filthy dairies in and around the city. The city chemist maintained that the city dairies were in good condition, but the investigation rather startled him by its disclosures, and he joined forces with the state commissioner for a general clean-up of the dairies. Thus far 328 gallons of formaldehyd milk have been destroyed, several dairies have been refused permission to sell milk to distributors and twenty-nine dairymen indicted for selling impure milk. In fining three of these offenders the court said the practice of selling impure milk was worse than murder; the other cases were continued. At the City Club on September 13, Dr. John Zahorsky, Mr. Bedal, an attorney, Mr. Lange, a milk dealer, and Dr. Max C. Starkloff, health commissioner, spoke on the subject. The result of these efforts for a pure milk-supply showed that little had been done because of legal complications and the crux of the situation was well stated by Mr. Bedal and Dr. Starkloff who declared that the only effective method of securing clean milk was to establish a system of licensing the dairies by the board of health, such license to be revokable by the board. The dairymen have successfully resisted previous efforts to establish this system. At present action against refractory dairymen can be had only by the tedious and utterly inadequate procedure of prosecution in the courts.

NEW MEXICO

Personal.—Dr. Lewis Clinton Day has been transferred from the position of physician to the San Juan Indian Agency, Shiprock, and has been made resident physician at the Haskell Indian Institute, Lawrence, Kan.

State Society Meeting.—The thirtieth annual meeting of the New Mexico Medical Society was held in Las Vegas, September 6-9. Roswell was selected as the next meeting place, and the following officers were elected: president, Robert L. Bradley, Roswell; vice-presidents, Drs. Le Roy S. Peters, Silver City; M. F. Marais, Las Vegas; James J. Shuler, Raton; secretary, Dr. Robert E. McBride, Las Cruces; treasurer, Dr. Frank E. Tull, Albuquerque; councilor, Dr. Edwin B. Shaw, Las Vegas; delegate to the American Medical Association, Dr. William R. Tipton, Las Vegas; alternate, Dr. Francis T. B. Fest, Las Vegas. During the session the Guadalupe County Medical Society and the Valencia Society were chartered.

NEW YORK

New Hospital.—A hospital was formally opened September 2, at Babylon. The building contains twenty-five ward beds and two private rooms and is well equipped.

Death-Rate in the State.—During July the total number of deaths in the state from all causes decreased by 438. The number of deaths of infants under 1 year was 2,590, while for July, 1910, it was 3,486. The percentage of lessened infant mortality appears to be greater in the cities than in the rural districts. Pneumonia and other respiratory diseases caused 864 deaths during July, 1911, while deaths from this cause for 1910 were 978. In July, 1911, pulmonary tuberculosis claimed 1,101 victims, 650 of whom died in Greater New York. The deaths from typhoid fever show an increase over those of the previous year. In July, 1910, there were 486 cases of typhoid fever reported, with 94 deaths, while in July, 1911, there were 641 cases with 125 deaths.

Regents to Require Full-Time Instructors.—At its last meeting the board of regents of the University of the State of New York amended its rule and now requires, that after Oct. 1, 1912, a medical college, in order to be registered in that state as maintaining a proper medical standard, must have at least six full-time salaried instructors, giving their full time to medical work; must have a graded course of four full years of college work in medicine, and must require for admission not less than the usual four years of academic or high school preparation, or its equivalent, in addition to the pre-academic or grammar school studies. This agrees with the definition of a medical college adopted in 1910 by the Council on Medical Education of the American Medical Association.

New York City

Work of the Season at Sea Breeze.—Junior Sea Breeze, the [illegible] for sick babies, conducted by the [illegible] the Condition of the Poor, closed [illegible] 7. The visiting nurses made 4,098 visits during the summer and instructed 1,321 mothers.

Two Physicians Have Septicemia.—Dr. Edward H. Quinn is in a very serious condition as a result of blood-poisoning contracted while operating on a ward patient in St. John's Hospital.——Dr. John A. Bodine, who was called in to operate on Dr. Quinn, developed septicemia the day following the operation. Dr. Bodine's condition has not been regarded as serious.

School Children Have Poor Teeth.—The first report of the School Dental Hygiene Council, which was appointed about a year ago to make an examination of school children's teeth, shows that about 60 per cent. of those so far examined have defective teeth. As a result of this investigation it is believed that there will be a regular system of dental inspection and clinics for the schools.

Inebriety Board Holds Meeting.—The recently-appointed Inebriety Board held its first business meeting September 12. The board has decided to call on the police to furnish data as to all arrests for intoxication after October 1. It was also decided to acquire land within 35 miles of New York City for a site for three hospital buildings, the cost of the site and buildings to be about $550,000.

Smoke Nuisance Abated.—New York is practically free from the smoke nuisance and this is due to the work of the Health Department in enforcing the amendment to the sanitary code which went into effect a little over a year ago. During this time 2,000 arrests have been made and $6,000 has been collected in fines. This result has been accomplished by compelling all who burn soft coal to use smoke consumers.

Cholera in New York City.—During 1911, steamers arriving from Italy brought cholera to New York City, the first case arriving on the *Carpathia*, June 7, and the last, up to the present time, on the *Koenig Albert*, August 17. So far forty-four cases have been stopped at quarantine. In the city only three cases were found. This is the first time since 1892 that the sanitary authorities have been called on to deal actively with Asiatic cholera.

Typhoid in the Bronx.—For the seven weeks previous to September 9, there were 180 cases of typhoid fever in the Bronx as against eighty for the same period of 1910. Since January 1 there have been twenty-two cases in that borough as against 178 for the corresponding time in 1910. The typhoid situation in the greater city has practically cleared up except in the Bronx. Up to the year ended September 9 there have been 1,898 cases in the greater city since January 1, as against 1,963 last year.

Harvey Society Lectures.—The Harvey Society has secured the following lecturers for the coming season: Prof. Walter B. Cannon, Harvard Medical School; Prof. R. H. Chittenden, Yale University; Dr. Simon Flexner, Rockefeller Institute; Prof. H. S. Jennings, John Hopkins University; Prof. Albrecht Kossel, University of Heidelberg; Prof. H. F. Osborn, Columbia University; Dr. James J. Putnam, Harvard Medical School; Prof. T. W. Richards, Harvard University; Prof. W. T. Sedgwick, Massachusetts Institute of Technology; Dr. William S. Thayer, Johns Hopkins Medical School, and Prof. Verworn, University of Bonn. The following lectures will be delivered during October: "Local Specific Therapy of Infections," by Dr. Simon Flexner, October 7; "The Chemical Structure of the Cell," by Prof. Albrecht Kossel, October 14; and "Anesthesia," by Prof. Verworn, October 28.

Personal.—Dr. Simon Flexner, director of the laboratories of the Rockefeller Institute of Medical Research, has been awarded the *Cameron Prize in Practical Therapeutics* by the University of Edinburgh. The award was made in recognition of Dr. Flexner's work in cerebrospinal meningitis and its treatment with antimeningitis serum. In accordance with custom Dr. Flexner has been invited to deliver an address at the University of Edinburgh some time during the coming academic year.——Drs. Henry W. Frauenthal and Charles L. Dana have returned from Europe.——The country home of Dr. Charles McBurney at Stockbridge, Mass., was robbed, September 13. The articles taken were mostly jewelry and the loss is estimated at $5,000.——Dr. Samuel J. Meltzer, president of the Rockefeller Institute for Medical Research, has been elected a member of the German Imperial Academy of Natural Sciences.

Buffalo

Cornerstone Laid.—The cornerstone of the New German Deaconess Hospital was laid with appropriate ceremony, September 10.

Crusade Against Milkmen.—The department of health has instituted a crusade against milkmen who sell milk which does not come up to the standard requirements, or in other words, is adulterated. After due notice, warrants were sworn against about fifty milkmen.

Personal.—Dr. Matthew D. Mann, Dr. Irving M. Snow and Dr. George A. Himmelsbach, have returned from Europe.——Dr. Burton T. Simpson, Dr. Maud J. Frye and Dr. Charles A. Bentz have gone abroad.——Dr. Otto R. Eichel has been appointed chief of the tuberculosis division of the Bureau of Vital Statistics.

PENNSYLVANIA

Tuberculosis Crusade.—The directors of the Pennsylvania Society for the Prevention of Tuberculosis, September 13, agreed to arrange for a state exhibit by means of which the unsanitary conditions of many houses will be shown. The exhibition will be given in a number of cities and towns in the state during the winter.

Inspection of School Children.—State Health Commissioner Dixon is preparing to make the medical inspection of school children authorized by the new school code. The inspections will be made in 785 school districts, which means that 250,000 children will receive the direct benefits of this important work. The inspectors will also make a thorough investigation of the sanitary conditions existing at the schools. They will be instructed to note the age and sex of the pupil, the condition of sight, hearing, respiration, skin, teeth, cervical glands, contagious diseases, pulmonary tuberculosis and deformities. In recording the deformities they will be classified as those of the spine, the chest and the extremities. Those of the extremities will be further described as congenital or acquired. Each eye will be tested separately, using Snellen's chart at 20 feet. The presence of blepharitis, conjunctivitis, iritis or trachoma or any affection of the cornea will be observed. Each ear will likewise be tested separately for accuracy of hearing by whispering at 20 feet. The presence of a discharge from either ear will be watched for and its nature observed. Defective teeth and nasal breathing will be noted. Enlargement of the cervical glands will be observed. With regard to nervous conditions the existence of chorea or epilepsy will be stated, and the general condition of nutrition. If indications of present or recent contagious disease are found, note will be made of the fact and the exclusion of the child and its brothers and sisters at once ordered. Under no circumstances will the medical inspector advise as to the selection of a physician or communicate with the family of a pupil personally with regard to the results of the examination, all reports to the family being made directly from the department. On receiving the reports at the central bureau in Harrisburg, the chief medical inspector and his assistants will go over them very carefully and letters will be written to the parents of children in whom physical defects have been found, calling attention to these defects and suggesting that the child be taken to the family physician for more detailed examination and treatment.

Philadelphia

Resignations.—Dr. Daniel W. Fetterolf has resigned as demonstrator of chemistry and toxicology in the University of Pennsylvania, to accept the position of acting assistant surgeon in the U. S. Army, with a permanent station in New York.——Dr. Howard T. Karsner has resigned as demonstrator of pathology in the same institution to accept the position of assistant professor of experimental pathology in Harvard University.——Dr. Borden S. Veeder, assistant demonstrator of pathology in the University of Pennsylvania, has resigned in order to accept the position of assistant in the department of pediatrics in Washington University, St. Louis.

Baby Hospitals Successful.—The Race Street Pier, which opened on June 15, with thirty-five beds and nursed back to life fully 500 babies during the summer, closed its season, September 15. The Wynnefield Babies' Hospital and the Chestnut Street Pier will probably remain open until October 1, when the most active baby-saving campaign that has ever been carried out in this city will terminate for another year. The following statistics show the reduction in infant mortality. The number of children under 2 years of age who died of summer complaint during June, July and August, 1910, was 1,258, while in the corresponding months of this year, only 924 died, *a reduction of 234, or 18.6 per cent.*

Dental Clinic Opens.—The free dental clinic for the treatment of school children's teeth opened September 15. It is on the seventh floor of city hall and is under the charge of Dr. P. B. McCullough. The plan this year is to have the dentists visit the schools, examine the pupils and make a note of those whose teeth need attention. This note will be given to the teacher to forward to the parents, with a recommendation that the child either be sent to the family dentist or to the city hall clinic. After a child's mouth has been put in good condition, he is given a tooth brush and a box of tooth powder and is instructed in the care of the teeth. Last year 2,561 patients were treated in the clinic.

Contagious Diseases Hidden.—A reduction in the mortality from most of the preventable diseases is noted for the first eight months of this year as compared with the same period of 1910, as follows: tuberculosis, 15 per cent.; typhoid fever, 23 per cent, and pneumonia, 12 per cent. This does not hold true with diphtheria and scarlet fever, however. Through the newspapers, Dr. Joseph S. Neff, director of public health and charities, has called attention to the continued prevalence of these diseases, and asks the public to cooperate with the health authorities in carrying out the instructions of physicians and health officers. He states that many persons, to avoid the necessary restrictions, do not send for a physician in order that the case may not be reported.

University Changes.—Announcement has been made of changes in the medical department of the University of Pennsylvania. A fuller course in toxicology is announced for the second year class, the second half of the term under the charge of Dr. John Marshall and his staff in the Hare laboratory. There will be also a department of physical therapy under the charge of Dr. R. Tait McKenzie. The changes in titles and duties in the teaching staff follow: Dr. Gwilym G. Davis assumes charge of orthopedic surgery in place of the late Dr. DeForest Willard; Dr. T. Turner Thomas becomes associate professor of applied anatomy; Dr. Alfred Stengel assumes the chair of medicine in place of Dr. David Edsall, resigned; Dr. M. Howard Fussell has been advanced to the chair of applied therapeutics, this department being created under the chair of medicine, in place of the position of professor of clinical medicine vacated by Dr. Alfred Stengel; Dr. George W. Norris is advanced to assistant professor in medicine; Drs. Ringer and Rose assume the duty of instructor and assistant instructor in physiological chemistry; Dr. Oscar H. Plant becomes demonstrator of pharmacology; Dr. R. M. Pearce has withdrawn from the chair of pathology and will confine his work to the chair of research medicine, and Dr. Allen J. Smith returns to the charge of the department of pathology, retaining at the same time the directorship of the laboratories of comparative pathology and tropical medicine.

UTAH

State Association Meeting.—The seventeenth annual meeting of the Utah State Medical Association will be held in Salt Lake City, October 4 and 5, under the presidency of Dr. Frederick W. Taylor, Provo. A banquet is to be given to the association by the Salt Lake County Medical Association, October 4. At the first session an address will be delivered by Dr. Joseph N. MacCormack, Bowling Green, Ky.

New Members of Faculty.—The new list of the faculty of the University of Salt Lake includes the following appointments and changes: Dr. Joseph Peterson, professor of psychology in the Brigham Young University, Provo, professor of psychology; Dr. Perry G. Snow, professor of anatomy; Dr. Ralph L. Byrnes, professor of bacteriology and pathology; and State Bacteriologist and Pathologist Dr. Charles T. Voorhies has been made acting dean of the school of medicine, and Dr. Henry A. Mattill has been promoted from assistant professor to associate professor of physiology and physiologic chemistry.

WASHINGTON

Personal.—Dr. John B. McNerthney, Tacoma, left for Europe, September 9.——Dr. John W. Mowell, Olympia, has been appointed chief physician of the state's commission on industrial insurance.——Dr. C. J. Brobeck has been appointed assistant health officer of Tacoma.——The board of education of Bellingham has declined to accept the resignation of Dr. William R. Gray as president.——Dr. James F. Cropp has been elected mayor of Walla Walla.

State Society Meeting.—At the twenty-second annual meeting of the Washington State Medical Association held in Spokane, September 5 to 7, the following officers were elected: president, Leon L. Love, Tacoma; president-elect, William C. Cox, Everett; vice-president, Dr. George N. McLoughlin, Seattle; secretary, Dr. Curtis H. Thomson, Seattle (reelected), and treasurer, Dr. Herbert E. Coe, Seattle. Tacoma was chosen as the place of meeting for 1912.

WEST VIRGINIA

Tri-County Society Meeting.—At the annual meeting of the Barbour-Randolph-Tucker County Medical Society, held in Elkins, September 5, the following officers were elected: president, Dr. Edmond J. Horgan, Jenningston; vice-presidents, Drs. Albert S. Bosworth, Elkins; E. Mendel Hamilton, Belington; secretary and treasurer, Dr. Ernest R. MacIntosh, Elkins; and censor, Dr. W. Hoddis Daniels, Elkins, reelected.

County Society Reorganized.—The physicians of Preston County met in Kingwood, August 23, reorganized and elected the following officers: president, Dr. Buckner F. Scott, Terra Alta; secretary and treasurer, Dr. A. G. DeFoe, Brandonville; and censors, Drs. Daniel J. Rudisill, Kingwood; Frank M. Fogle, Rowlesburg, and Dr. William F. Dailey, Terra Alta.

Antituberculosis Organization Chartered.—The Ohio County Anti-Tuberculosis League was chartered August 29, with offices in Wheeling. The league is given authority under the charter to own and transfer real property to the value of $50,000, and personal property to a similar amount, and to erect and maintain hospitals for the care of persons afflicted with tuberculosis. The incorporators are Drs. Harriet B. Jones, Eugenius A. Hildreth II, and William H. McLain, and Messrs. Jesse A. Bloch and Henry M. Russell.

WYOMING

State Society Meeting Indefinitely Postponed.—Dr. William H. Roberts, Sheridan, secretary of the Wyoming State Medical Society, announces that several unforeseen circumstances, including the failure of the Burlington system to complete its line to Thermopolis, have conspired to cause the indefinite postponement of the annual meeting of the society, which was scheduled to be held at Thermopolis, September 4 and 5.

GENERAL NEWS

Societies to Meet.—Among the society meetings that are to occur in September and October are the following:

Amer. Acad. of Ophthal. and Oto-Laryngol., Indianapolis, Sept. 25-27.
Amer. Assn. of Obstet. and Gynecol., Louisville, Ky., Sept. 26-28.
American Association of Railway Surgeons, Chicago, Oct. 18-20.
American Urological Association, Chicago, Sept. 26-27.
Assn. of Military Surgeons of United States, Milwaukee, Sept. 26-29.
Delaware State Medical Society, Lewes, Oct. 10.
Idaho State Medical Association, Boise, Oct. 11-13.
Indiana State Medical Association, Indianapolis, Sept. 28-29.
Kentucky State Medical Association, Paducah, Oct. 24-26.
Medical Assn. of the Southwest, Oklahoma City, Okla., Oct. 10-12.
Medical Society of Virginia, Richmond, Oct. 24-27.
Michigan State Medical Society, Detroit, Sept. 27-28.
Minnesota State Medical Association, St. Paul, Oct. 5-6.
Mississippi Valley Medical Association, Nashville, Tenn., Oct. 17-19.
Nevada State Medical Association, Reno, Oct. 10-12.
Pennsylvania State Medical Society, Harrisburg, Sept. 25-28.
Utah State Medical Association, Salt Lake City, Oct. 4-5.
Vermont State Medical Society, Burlington, Oct. 12-13.

FOREIGN NEWS

International Congress of Pathology at Turin, Italy.—This congress has been scheduled to meet at Turin, October 1 to 5, and extensive preparations have been made for the scientific work.

Tuberculosis Congress Postponed.—The postponement of the Seventh International Tuberculosis Congress at Rome, Italy, to April, 1912, meets with general approval on account of the prevailing dread of cholera in southern Europe. The congress was to have been held the last week of this month—September—and the work had already been well organized and numbers of important papers received.

Centennial of Christiania University.—The *Norsk Magazin for Lægevidenskaben* issues a souvenir volume, in honor of the centennial of the university at Christiania, reviewing the history of medicine in Norway during the last hundred years. It is profusely illustrated with views of old and new hospitals and asylums and portraits of the leading physicians, especially the members of the medical faculty. The work is from the pen of S. Laache, professor of internal medicine at the university.

The Zander Festschrift.—The tenth volume of the *Archiv für Orthopädie* is dedicated to Gustav Zander on the occasion of his seventy-fifth birthday. The first nine articles describe Zander's work and apparatus for medico-mechanical exercises and the opening of his institute at Stockholm, Sweden, in 1865 and of similar institutions on this model in other countries. The benefits of these mechanico-therapeutic exercises in the various internal infections are emphasized by different authors. From 1880 until recently Zander was docent of medical gymnastics at the university of Stockholm.

LONDON LETTER

(From Our Regular Correspondent)

LONDON, Sept. 9, 1911.

Reform of the Naval Medical Service

Considerable reforms have been introduced into the naval medical service, corresponding to those introduced some years ago into the army service. The rate of pay has been slightly increased for surgeons by about $180 per annum and in the higher grades proportionately. Officers are permitted to retire into private life at an earlier period than heretofore. After serving four years a naval surgeon may pass into the reserve, taking a gratuity of $2,500 and incurring no other liability than being called on to serve in time of war or emergency. This liability places no impediment in the way of private practice. But the most important reform is the establishment of a naval medical school at Greenwich. It is considered essential for the scientific development of the service that it shall possess a school of instruction and research in the vicinity of London, where it will be in close touch with the principal civil medical schools and with the army medical school at Millbank. It has therefore been decided to establish a naval medical school at the Royal Naval College, Greenwich, in close proximity to the Seamen's Hospital and the London School of Tropical Medicine. It will thus be in a position to carry out its educational and scientific work in close connection with these establishments. There are already at Greenwich excellent chemical and physical laboratories, and the additional laboratories required for medical research will be provided in the college buildings. The following new offices have been created as the nucleus of an instructional staff—a professor of bacteriology and clinical pathology, who will be a fleet surgeon with a special allowance of $750 a year, and a professor of hygiene under the same conditions. The latter will reside at the college and will be in charge of naval medical officers taking courses and for this duty will receive an extra allowance of $250. Certain alterations have been made in the regulations for the selection and examination of candidates for naval surgeons. The course of instruction after entry has been lengthened from four to six months. At the termination of the course there is an examination. An officer who fails to pass this is given a second trial and if he fails again his services are dispensed with. In future, postgraduate instruction of naval medical officers will consist of two distinct courses—a six months' course before advancement to staff surgeon and a second course for officers of not less than 14 years seniority.

The subjects of study and examination will be: (1) *Compulsory:* clinical medicine and surgery, operative surgery, anesthetics, ophthalmology, clinical pathology and hygiene. (2) *Optional:* bacteriology, throat, nose and ear diseases, and skiagraphy. The second course is designed for the purpose of affording to senior officers the opportunity of refreshing their general knowledge of surgery and medicine and familiarizing themselves with modern improvements. A small medical library of value not exceeding $50 will be supplied to each ship carrying a medical officer.

Acute Poliomyelitis Rendered Notifiable

The outbreak of acute poliomyelitis in this country, mentioned in a previous letter to The Journal, has caused the London County Council to declare this disease notifiable to the local health officers under a penalty of $10.

PARIS LETTER

(From Our Regular Correspondent)

Paris, Sept. 8, 1911.

The Coming International Sanitary Conference

The International Sanitary Conference mentioned in a previous letter (The Journal, Aug. 5, 1911, p. 492) will meet at Paris beginning October 10, with a view to revising the articles of the conference of 1903 for the prevention of the epidemics of cholera or the plague. It will be composed of representatives from about forty states, instead of the twenty-three governments which took part in a similar conference held at Paris in 1903 which drew up the articles of the sanitary convention signed December 3 of the same year.

Agitation Among the Nurses

For some time there has been strong discontent among the male nurses, and a strike has even been declared in one of the insane asylums at Aix-en-Provence. The grievances of the nurses are to be found principally in the poorly prepared food and the unhygienic dormitories assigned to them. They also demand a discontinuance of the practice of setting aside of a portion of the salaries of probationary nurses in view of future retirement. The *Journal Officiel* recently published a very interesting report of the inspector-general of the administrative service of the ministry of the interior which disclosed the fact that in many asylums the nurses receive only $60 (300 francs) a year to start with, which may be raised to a maximum of $100 (500 francs) a year. This, as the inspector-general remarks in his report, is a smaller salary than is paid to farm hands. This low salary also explains the insufficient training of the nurses, the difficulty in recruiting the whole body, which, as Dr. Charron, director of the asylum at Dury-les-Amiens, says, is composed to a very large extent of a wandering, unstable element without interest in their work, without any professional pride, and often without even personal dignity, a class of outcasts—lazy, intemperate, and dissolute; discharged working-men or servants.

Encouraging Large Families

A departmental league of the fathers and mothers of large families has just been established at Troyes. The president has given out interesting information about the work to be undertaken and has disclosed the generous offer of Mr. G. Verbeckmoes, the proprietor of the working-men's houses at Clichy (on the Seine). He introduced into his contracts the following clause: "After a year of residence in the house, each occupant, paying less than $120 (600 francs) rent, will be allowed a rebate of a half term's rent each time that his wife is confined."

BERLIN LETTER

(From Our Regular Correspondent)

Berlin, Aug. 31, 1911.

Classical Courses in High School and College

Some water has been mingled with the wine of the hope which I expressed in my comments on the Kaiser's speech, in my last letter, regarding the appreciation of the classical course in our higher schools, according to an official statement of the North German *Allgemeine Zeitung.* In this communication attention is directed to the fact that the words of the Kaiser must not be regarded as of general application, but rather as intended only for the pupils of the first grade of the classical gymnasium at Cassel. In other words, it should be stated that the Emperor now, as formerly, adheres to his high estimate of the technical school education (*Realschulbildung*) in general. A contradiction, nevertheless, does exist between this subsequent explanation and the words of the Kaiser. It is explained, like most of the inconsistent statements which are found in the speeches of the Kaiser, by his impulsiveness in consequence of which he followed the thought of the moment without reference to his former assertions of its general relation.

That the danger, to which I have called attention, of a further depreciation of classical studies, especially the study of Greek in our gymnasiums, actually exists, is shown by a statement just published by the faculty board of the university of Giessen. This statement is as follows:

"In view of the recent repeatedly occurring efforts to abandon the study of Greek in classical gymnasiums or to materially restrict it, we declare that we must regard it as equivalent with the abandonment of the classical high-school course as a whole. While it is far from our purpose to attack the equal estimate put on the technical gymnasiums and the technical colleges in comparison with the classical gymnasia, we must still, as formerly, accord to the classical gymnasium a special importance in the preparation for all university studies, and recognize in any serious injury to such schools a grave danger for education in general. This is especially true for all important and broad subjects for which a thorough insight into the nature and connections of historical development form the foundation and necessary preliminary. We, therefore, hold it our duty to enter our protest, as early and as emphatically as possible against those injurious attempts.

"We furthermore protest against making the school responsible for the injury of our youth which we can only regard as the results of modern conditions of living, and we assert that exactly in reference to the struggle against these injurious consequences we regard any further letting down in the requirements of the schools as dangerous." This statement forms in a certain sense an answer to the publication in the North German *Allgemeine Zeitung.* If the faculties of other universities should express themselves in the same sense as that of Giessen, it is to be hoped that the authorities will thoroughly investigate the question of further school reform before the ideas which are now prevalent regarding a classical education are carried into effect.

Refusal of a Promotion

Dr. R. Geigel of Würzburg, professor extraordinary of internal medicine, has refused the title of regular professor, which has just been accorded to him. The motive of this unusual step is so far unknown; it is possible that the investigator who is now in his fifty-ninth year is offended at the fact that instead of his being appointed successor of Professor von Leube, as was formerly announced, Professor Gerhardt has been chosen as director of the medical clinic. Such a conception must be regarded as entirely unjustified, for Geigel has not done work of sufficient note to give him any claim to such an appointment.

An Alleged Prussian Epidemic Bureau

An item appeared in the daily press, a short time ago, according to which a committee had been appointed under the cooperation of the medical section of the department of the interior and the war department as well as the imperial health office, which should have for its aim the foundation of a central station for the investigation of and campaign against epidemic diseases. The active work of this central station was stated to consist mainly in testing preparations which promise to be of service in the campaigns against the most frequently occurring epidemic diseases. According to information given me from an authoritative source, the entire announcement is the product of the overheated fancy of a reporter; at least nothing is known of such a foundation by those who are in a position to know most about it.

VIENNA LETTER

(From Our Regular Correspondent)

Vienna, Sept. 1, 1911.

Difficulties of Building the New Clinics

While the clinics of von Noorden and von Pirquet have been recently completed, and the first-named will be opened in a few days and the latter in October, the building of the remainder has suddenly become doubtful. The difficulty lies in the lack of money, both for building and for running the institutions. As has been explained in a previous letter, there is a certain corporate faction known as the "hospital fund" (Spitalsfonds), whose duty it is to provide hospital accommodations for needy patients. This "fund," though bankrupt for several years, is still in function because neither the municipality nor the local or central government acknowledge any responsibility for it, or for the existence of suitable hospital beds. Yet, the hospitals had to be kept running and the money required for this purpose was loaned to the famous bankrupt "fund"; a most amusing situation, were it not so sad. The conditions became unbearable at last and a cooperation of the famous fund with the three above-mentioned public forces brought about an arrangement by which the old hospital clinics should be transferred to the new General Hospital, and the funds necessary for this transfer should be obtained by the sale of real estate belonging to the old hospital. Thus the two gynecologic clinics, the clinic of von Noorden (medical), the pediatric and the rhino-laryngologic clinics were erected on a grand scale. The expenses of running are much higher than expected, also the building was much dearer than originally planned, and now the "fund" has no money for the necessary new clinics: two surgical, two medical, two dermatologic, one aural, two ophthalmologic clinics, one chemical and one pathologic-anatomic, besides a medicolegal institute. Already more than $4,000,000 have been expended and another $6,000,000 are wanted! The Spitalsfond has found out that it is not its duty to build any more clinics but that the ministry of education should do this; thus a deadlock has been produced. Meanwhile, the clinics remaining in the old hospital have made use of the space made vacant by the emigration of the four clinics now located in the new hospital, and the Spitalsfond asserts that they are not now in need of space for wards, and proposes to make the existing old wards over into laboratories, baths and lecture halls so that the necessity of new clinics could be done away with; for these expenses the funds are available. The news of the radical change of the old plan has caused much disappointment both in the public and among the profession, as well as in the teaching staff of the university. A conference between the mayor of Vienna, the representatives of the government and some banks has resulted in an arrangement by which sums would be furnished which would prevent this disgrace to the Vienna Medical School. But here again, the question is whether bureaucratic red-tape will not spoil this arrangement. The professors have taken the matter up and it is possible that serious consequences may follow if the new hospital should remain incomplete.

Marriages

William Seaman Bainbridge, M.D., New York City, to Miss June Ellen Wheeler of Yonkers, N. Y., at Grenheim, September 9.

Nathaniel Robert Mason, M.D., Boston, Mass., to Miss Eunice Ireland of Winchester, Mass., at North Conway, N. H., August 31.

Frank Caryl Totten, M.D., Morristown, S. D., to Miss Charlotte Louise Hutton of Sioux City, Ia., September 1.

Arthur William Stillians, M.D., Chicago, to Miss Therese Spitler of Vienna, Austria, in New York City, July 24.

James H. Kenyon, M.D., to Josephine S. Hemenway, M.D., both of New York City, at Glasgow, Mo., September 7.

Nathaniel M. Baskett, M.D., Moberly, Mo., to Miss Margaret Gore of Fulton, Mo., in London, Eng., August 26.

Upton Sharretts Reich, M.D., Bridgeport, Conn., to Miss Lillian H. Kessner, at Waterbury, Conn., August 30.

Fred McKemy Ruby, M.D., Union City, Ind., to Miss Ethelyn Marie Butcher, at Richmond, Ind., September 7.

Herbert Bancroft Priest, M.D., Groton, Mass., to Miss Edith Houghton of Littleton, Mass., September 6.

Gustav Leonard Kaufmann, M.D., Chicago, to Miss Muriel Gregory of Fredericton, N. B., Can., September 4.

George Luther Davenport, M.D., to Miss Eva Beulah Griffith, both of Chicago, September 12.

Harry Bailey Chalfant, M.D., Philadelphia, to Miss Elva Storey of Landenberg, Pa., July 27.

Edward G. Birge, M.D., Altoona, Pa., to Miss Edna Ebaugh, at Orangeville, Md., September 7.

Thomas Arneson, M.D., to Miss Mabel Chandler, both of Frederic, Wis., August 20.

John Frederick W. Rost, M.D., to Miss Adela Peine, both of Minier, Ill., June 14.

Deaths

Thomas Dwight, M.D. one of the foremost anatomists of America, and successor to Dr. Oliver Wendell Holmes as Parkman professor of anatomy in Harvard Medical School; died at his home in Nahant, Mass., September 8, aged 67. Dr. Dwight took both his academic and his medical course at Harvard, graduating from Harvard Medical School in 1867. After two years of study abroad, he returned to the United States, and commenced to practice in Boston, and became instructor in comparative anatomy at Harvard Medical School in 1872, and was at the same time lecturer on and professor of anatomy in Bowdoin College, Brunswick, Me. From 1874 to 1883 he was instructor in histology in his alma mater and for the last three years of that time also an instructor in topographical anatomy. In 1883 he was made Parkman professor of anatomy, and continued in this position until his death. From 1873 to 1878 Dr. Dwight was editor of the *Boston Medical Journal.* His society membership included the Massachusetts Medical Society, the Association of American Anatomists, of which he was once president, and the American Society of Naturalists. He contributed numerous papers to the literature of human and vertebrate anatomy, and also was author of a work on "Anatomy of the Head," which appeared in 1876, and "Description of Frozen Sections of a Child," which was published in 1881; and a monograph on "Variations of the Bones of the Hand and Foot," in 1907.

Frank E. Waxham, M.D. for many years well-known as a laryngologist and rhinologist of Chicago, but for several years a resident of Denver, Colo., died in Sugar City, September 4, from cerebral hemorrhage, aged 59. Dr. Waxham was a native of Laporte, Ind., and took his medical course in the Northwestern University from which he was graduated in 1878. He commenced practice in Chicago, and became rapidly prominent as a specialist on diseases of the throat and nose. In 1893, on account of his wife's health, he was obliged to move to Colorado. He settled in Denver where he was professor of medicine, clinical medicine, laryngology and rhinology, in the University of Colorado, Boulder. He was a member of the American Medical Association and the state medical societies of Illinois and Colorado. He was a member of the medical staff of St. Joseph's Hospital, Denver, laryngologist and rhinologist to the University Hospital, Central Free Dispensary, National Jewish Hospital, and Children's Hospital and consulting laryngologist and rhinologist to the Denver City and County Hospital.

William Flynn, M.D. Louisville (Ky.) Medical College, 1876; once president of the Grant County (Ind.) Medical Association, and a member of the faculty of Indiana Medical College for many years, and later emerit [illegible] ne in the Indiana University School of [illegible] died in his apartments in Marion, September 1, from cerebral hemorrhage, aged 59. At the funeral of Dr. Flynn, the active pallbearers were members of the profession of Grant County, and the county medical society, at a special meeting, adopted resolutions deploring its loss in the death of Dr. Flynn.

Maurice Clarke Dwight, M.D. Harvard Medical School, 1882; of Haverhill, Mass., a member and once vice-president of the Massachusetts Medical Society; for twenty-two years secretary of the Essex North District Medical Society; formerly a member of the Haverhill (Mass.) board of health and a member of the local pension board; formerly consulting physician to the Danvers State Hospital; surgeon and chief of staff of the Hale Hospital; and secretary and treasurer of the Haverhill Medical Club; died at Hathorne, Mass., September 7, aged 59.

George Halsey Peets, M.D. University of Pennsylvania, Philadelphia, 1860; of Fort Adams, Miss.; chief surgeon of brigade in the Confederate service throughout the Civil War; at one time representative in the legislature from Wilkinson County; died at his country home "The Valley," in the western part of Wilkinson County, May 4, from carcinoma of the rectum, aged 73.

Benjamin Edson, M.D. New York University, New York City, 1873; a member of the Medical Society of the State of New York, and ever since his graduation a practitioner of Brooklyn; physician to the Home for Destitute Children, and for several years principal of Public School No. 14; died at his home, September 6, from heart disease, aged 70.

William Monroe Burroughs, M.D. Medical College of the State of South Carolina, Charleston, 1859; of Pineville, Ala.; a member of the Medical Association of the State of Alabama; died in Nadawah, in October, 1910, from senile debility, aged 74.

Lewis Wheeler Rose, M.D. New York University, New York City, 1887; a member of the American Medical Association, and the New York State Pathological Society; once president of the Monroe County Medical Society; for two years surgeon to the New York State Soldiers' and Sailors' Home, Bath; from 1882 to 1898 physician to the State Industrial Home; a member of the surgical staff of the Rochester General Hospital; died at his home in Rochester, August 29, from heart disease, aged 45.

George Dana Towne, M.D. New York University, New York City, 1878; of Manchester, N. H.; a member of the American Medical Association, and once president of the Hillsboro County (N. H.) Medical Society, and secretary of the New Hampshire Surgical Club; for many years visiting surgeon to the Elliot Hospital, and a trustee of the State Normal School, Plymouth; died at his summer home in Dunbarton, N. H., September 11, from cerebral hemorrhage, aged 57.

Alfred W. Mitchell, M.D. Washington University, St. Louis, 1879; a member of the American Medical Association and local surgeon of the Frisco system at Humansville, Mo., a member of the legislature for two terms from Polk County; died suddenly, while working in his garden, September 4, from heart disease, aged 55.

Carroll M. Baggarly, M.D. University College of Medicine, Richmond, Va., 1901; a member of the American Medical Association; associate professor of ophthalmology in his alma mater, and medical director of the public schools of Richmond; died in the Virginia Hospital, Richmond, September 3, from typhoid fever, aged 38.

John E. Lockridge, M.D. Medical College of Virginia, Richmond, 1863; a Confederate veteran; for several years a member of the staff of the Indiana Asylum for the Deaf and Dumb, and a practitioner of Indianapolis; died at the home of his sister-in-law in Nevada, Ia., August 13, from senile debility, aged 81.

George Fairlamb Harris, M.D. University of Pennsylvania, Philadelphia, 1864; a member of the American Medical Association, and a veteran of the Civil War; for several years vice-president of the First National Bank of Bellefonte, Pa.; died at his home in that city, September 11, from heart disease, aged 68.

John Taylor Gilman Nichols, M.D. Harvard Medical School, 1859; of Cambridge, Mass.; a member of the American Medical Association; acting assistant surgeon in the Army during the Civil War; at one time visiting physician to the Cambridge Hospital; died at Little Boars Head, N. H., August 27, aged 74.

Leonidas Franklin Wilbur, M.D. Harvard Medical School, 1854; for half a century a member of the Ontario County (N. Y.) Medical Society; and for many years president of the board of trustees of the Honeoye Public Library Association; died at his home in Honeoye, September 2, aged 79.

Justin de Lisle, M.D., Jefferson Medical College, 1882; of Springfield, O.; a member of the American Medical Association; while pursuing investigations regarding a serum for the cure of syphilis at the Pasteur Institute, Paris, France; died August 1, from arteriosclerosis, aged 52.

Isaac Buckeridge, M.D. Hahnemann Medical College, 1883; a member of the Wisconsin State Medical Society, and for several years a member of the council and health officer of Beloit; died at his home, August 30, from hypertrophy of the liver, aged 61.

Lorenzo D. Hamblett, M.D. Eclectic Medical College of Maine, Lewiston, 1885; for more than fifty years a practitioner, and since 1871 a resident of Somersworth, N. H.; died at his cottage in York Beach, Me., August 24, aged 84.

Harland Edgar Beers, M.D. Willamette University, Salem, Ore., 1890; a member of the American Medical Association and one of the oldest practitioners of Sherman County, Ore., died at his home near Wasco, March 25, aged 42.

James C. Melville (license, Michigan, years of practice, 1900); assistant surgeon of volunteers during the Civil War, and for thirty-three years a practitioner of Grand Rapids, Mich.; died at his home, September 6, aged 71.

George Koenig (license, Neb., 1891) for more than forty years a practitioner of Richardson County; is said to have committed suicide August 18, by hanging himself from the limb of a tree while despondent, aged 72.

William S. Browne, M.D. Bennett Medical College, Chicago, 1875; formerly of Watseka, Ill.; a member of the Illinois State Medical Society; died at his home in Opolis, Kan., August 21, from cerebral hemorrhage, aged 67.

William T. Sherwood, M.D. University of Michigan, Ann Arbor, 1859; a retired practitioner of Ravenswood, Chicago; acting assistant surgeon in the Army during the Civil War; died at his home, September 1, aged 79.

Samuel P. Seese, M.D. University of Pennsylvania, Philadelphia, 1874; of wide reputation as a botanist and investigator of medicinal plants; died at his home in Lansdale, Pa., August 29, from heart disease, aged 60.

Edward Parrish Thatcher, M.D. University of Michigan Homeopathic College, Ann Arbor, 1881; for two terms coroner of Wayne County, N. Y.; died at his home in Newark, N. Y., September 1, aged 53.

Arthur Kipp, M.D. Kentucky School of Medicine, Louisville, Ky., 1903; for several years a practitioner of British Honduras; died at his home in Louisville, September 1, from diabetes, aged 29.

Johiel H. Bonebrake (license, Kan., 1901) of Lecompton; twice a member of the state legislature; a practitioner since 1860; died at the home of his daughter in Overbrook, Kan., January 13.

Walter Henry Maynard, M.D. New York University, New York City, 1898; of New York City; a specialist on diseases of the throat and nose; died suddenly at his home, September 2, aged 45.

Samuel R. Kreidler, M.D. Hahnemann Medical College, Chicago, 1873; for many years a practitioner of Red Oak, Iowa; died at his home on a ranch near Moorcroft, Wyo., August 19, aged 63.

Julius Adolph Stegmair, M.D. New York University, New York City, 1886; a member of the Medical Society of the State of New York; died at his home in New York City, April 4.

Robert N. C. Tate, M.D. New York University, New York City, 1849; a member of the State Medical Association of Texas; died at his home in Gonzales, September 4, aged 84.

James W. Rock, M.D. Eclectic Medical College of the City of New York, 1876; formerly of New York City; died at his home in Utica, N. Y., August 24, from nephritis, aged 64.

Paul Robert Baer, M.D. Marion-Sims College of Medicine, St. Louis, 1893; of St. Louis; died in Herrnhut, Saxony, Germany, August 31, from cerebral hemorrhage, aged 55.

James G. W. Entwistle, M.D. Albany (N. Y.) Medical College, 1883; formerly of Chicago; died at his home in Canton, Ill., September 1, from pernicious anemia, aged 69.

Hamilton Byron Griswold, M.D. University of Vermont, Burlington, 1886; a veteran of the Civil War; died at his home in New Milford, Conn., June 24, aged 64.

David Mitchell, M.D. Victoria College, Coburg, Ont., 1869; a pioneer practitioner of Olympia, Wash.; died at the Canyon Hotel, Yellowstone Park, Mont., August 30.

Jacob Weber, M.D. University of Pennsylvania, Philadelphia, 1858; of Philadelphia; died in Cape May, N. J., August 30, from heart disease, aged 86.

Phoebe Low, M.D. Eclectic Medical College of Pennsylvania, Philadelphia, 1872; died at her home in Liberty, N. Y., August 21, from cerebral hemorrhage, aged 73.

Silas Wright Frame, M.D. Bellevue Hospital Medical College, 1875; a veteran of the Civil War; died at his home in Belleville, N. Y., August 27, aged 69.

Henry L. Schilling, M.D. Tulane University, New Orleans, 1890; formerly of Magnolia, Miss.; died at his home in Hot Springs, Ark., September 2, aged 56.

A. Herbert Bayard, M.D. Albany (N. Y.) Medical College, 1889; health officer of Cornwall-on-the-Hudson, N. Y.; died at his home, August 31, aged 42.

William Harmon Miller, M.D. Jefferson Medical College, 1893; formerly of Rockport, Tex.; died at his home in San Antonio, August 29, aged 44.

Clarence N. Mitchell, M.D. Baltimore Medical College, 1902; of Lawrence, Mass.; died at the Cottage Hospital in that city, August 26, aged 31.

George David Greenslate, a practitioner since 1876; died at his home in Willmathsville, Mo., July 12, from carcinoma of the liver, aged 62.

George F. Chapman, M.D. University of Louisville (Ky.), 1890; died at his home in Centertown, Ky., recently from nephritis, aged 57.

Thompson M. Wells, M.D. Hahnemann Medical College, Philadelphia, 1875; died at his home in Bellaire, O., August 31, aged 58.

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession.

THE CHARGE AGAINST DR. WILEY

Extracts from the Testimony Given Before the Congressional Committee

(Continued from page 997)

THE DENVER MEETING

[In August of 1909 the thirteenth annual convention of the State and National Food and Dairy Departments met in Denver. At the previous meeting, held at Mackinac Island, Mich., Aug. 4-6, 1908, the association had adopted resolutions expressing its regret that the cooperation of the Secretary of Agriculture in establishing standard for the enforcement of food laws, had been withdrawn. At the 1909 meeting in Denver strenuous efforts were made by the Secretary and his friends to control the convention, to prevent the passage of resolutions denouncing the findings of the Remsen Board, and to control the election of officers. The extracts from the testimony which follow show how the resources of the Department of Agriculture were used to secure the presence of as many adherents of Wilson and McCabe as possible and to influence the votes of as many of the delegates as could be swayed. The first extract is from Professor Remsen's testimony, and shows how Secretary Wilson arranged to have the Referee Board attend the Denver meeting and how its influence was used. Part of Professor Remsen's evidence is given below:]

DR. REMSEN'S TESTIMONY

Mr. Floyd. Did you attend the convention of State and National Dairy and Food Departments at Denver in 1909?

Dr. Remsen. Yes, sir; on the way back from California I stopped there.

Mr. Floyd. Did you attend on your own volition, or were you directed by the department to attend?

Dr. Remsen. I was not directed; I was requested.

Mr. Floyd. You were requested to attend?

Dr. Remsen. Yes.

Mr. Floyd. How long did you remain at Denver during that convention?

Dr. Remsen. Two or three days; I am not sure just exactly how long.

Mr. Floyd. What was the purpose of that convention, and what were the questions discussed there? Did they relate to pure foods?

Dr. Remsen. Well, I do not know much about the association. I do know that I was asked by the president of the association to give an address on the subject of the work of the referee board, I think, or at least it had reference to the benzoate question, and after finding I could stop there conveniently on the way from California and that the other members of the board could do the same, I accepted the invitation. The association discussed all sorts of questions pertaining to things of which I have no knowledge, but I do know that they took up this benzoate question in rather an active way, and I suppose it was felt by the Secretary that it was desirable to have some one there to explain what it all meant. They seemed to be going on the wrong track, so far as we could gather. They got some wrong impressions of the thing and the nature of the work, or what we were appointed for, or what we were doing, and it did seem wise not to let them go too far that way without some explanation from us, which we gave in a dignified way, I think I can safely say.

Mr. Floyd. And the expenses of yourself and the other members of the board for this trip to California and this trip to the convention in Denver were paid by the department?

Dr. Remsen. Yes. Of course the trip to the convention amounted to very little. That was simply stopping over.

Mr. Floyd. You state that you addressed the convention yourself. Did any of the other members of the board address the convention; and if so, who?

Dr. Remsen. Dr. Chittenden, Dr. Long, and Dr. Herter all addressed the convention, at the request of the president of the association, Mr. Emory.

Mr. Floyd. I will ask you to state if in the address you made before the convention on the question of benzoate of soda you made a defense of the use of benzoate of soda?

Dr. Remsen. No, sir.

Mr. Floyd. You just discussed the findings?

Dr. Remsen. I discussed the general method of procedure which we had followed. I have nothing to do with the use of benzoate of soda. We were not asked to decide whether it was a good thing to use or not, and we have never expressed ourselves upon that point.

Mr. Floyd. What was it, then, that you were asked to decide?

Dr. Remsen. Whether the use of benzoate of soda in small doses and in large doses is or is not injurious to the human system. That was the end of the inquiry so far as we were concerned.

. . . .

The Chairman. Your expenses at Denver were also paid by the Department of Agriculture?

Dr. Remsen. We went, as I said yesterday, to California for an important purpose, looking into the sulphuring process, and on our way back we stopped there. We did make a little effort to time our trip back so that we could attend that meeting, because we had been asked to give addresses. We were asked by the president of the association. We stayed there possibly three days. I am not sure whether it was two or three, but not more than three. The slight expense of the board during that period in the way of traveling expenses was paid by the——

The Chairman (interposing). You gave an address there?

Dr. Remsen. Yes.

The Chairman. And the purpose of that address was to explain and defend the report you had made to the Secretary of Agriculture?

Dr. Remsen. I did not defend the work. I didn't think that was my business. The report had been made. But I did do this. I explained, somewhat as I have explained to this committee yesterday, how the board came into existence, and very little else. I don't think that address was ever published. Then, I may say that after that the work of the board was attacked very violently by Dr. Reed of Cincinnati, which was most astonishing to me. After that attack I felt it my duty to respond, which I did in measured manner, and I didn't say anything I would not repeat. I will add that to what I said yesterday, because I made really two addresses there The other members of the board I think did not answer the attack. I think they were satisfied with my answer.

The Chairman. In making either one of those addresses did you go beyond the official work of your board and defend the use of benzoate of soda as a preservative of food?

Dr. Remsen. No, sir.

[Solicitor McCabe not only attended the Denver meeting at government expense and, as he naïvely says, "cast the vote for the Department," but also—as his evidence shows—made an earlier trip west, of which, at first, he could not remember any of the details. Under the cross-examination of Dr. Wiley's representative, Mr. McCabe was forced to admit that he went west to line up votes for the Department of Agriculture, "to support the referee board's decision on the benzoate of soda question, as against the decision of the Bureau of Chemistry on the same question." A part of his testimony follows:]

MR. MCCABE'S TESTIMONY

Mr. Floyd. Did you attend a meeting of the Association of State and National Dairy Departments of the United States at Denver in 1909?

Mr. McCabe. Yes, sir.

Mr. Floyd. Did you take any part in the discussion or proceedings there?

Mr. McCabe. Yes, sir.

Mr. Floyd. Was there any question raised in that convention in regard to the use of benzoate of soda as a preservative?

Mr. McCabe. There was.

Mr. Floyd. Did you take any part or participation in the discussion of that question?

Mr. McCabe. I did.

Mr. Floyd. On what side?

Mr. McCabe. In favor of the ruling of the department. I have always been on that side.

Mr. Floyd. In favor of the ruling of the department. What was the occasion of your attending that convention? Did you go there in your official capacity?

Mr. McCabe. I went there by direction of the Secretary of Agriculture. The occasion of my attending was this. That meeting in Denver was held in 1909. The meeting the year before had been held at Mackinac, in the State of Michigan. That was in 1908. At the Mackinac meeting they held a secret session of the association. Not only was it a secret session barred to the public, although they were public officers attending there at public expense, either national or state, but they had a secret ballot. Among the resolutions that they adopted, among the resolutions which were reported by the committee on resolutions, was one vilifying and abusing the Secretary of Agriculture and questioning his good faith I was not at that meeting.

Mr. Floyd. Can you produce that resolution in this connection?

Mr. McCabe. I will tell you about that. I will come to that point. There were four or five department people there. When the resolution was reported, they could not bear to remain and see their chief slaughtered. So they asked to be excused and went out, I suppose with their handkerchiefs to their eyes, and the resolutions were adopted; that is, some resolutions were adopted. There were some resolutions reported in the papers, and the resolutions which were reported in the papers virtually and practically accused the Secretary of misapplication of funds. And the Secretary of Agriculture wrote to the secretary of the association and asked him for a copy of the resolutions, and he wrote repeatedly, and he was never able to get them. So when the Denver meeting was coming on the Secretary said, "We will go out there and we will have an open meeting, and we will see what they have to say when I am there." And we went out.

Mr. Floyd. And you went in your official capacity?

Mr. McCabe. Yes.

Mr. Floyd. At the direction of the Secretary?

Mr. McCabe. I did.

Mr. Floyd. Did other members of the Department of Agriculture attend?

Mr. McCabe. Yes, sir. There were a number of employees of the Bureau of Chemistry and a number of the employees of the Bureau of Animal Industry—Dr. Bigelow, Dr. Wiley; I think Dr. Kebler was there, and Dr. Melvin and Dr. Rawl, of the Dairy Division, I think were there.

. . . .

Mr. Davis. Very well. You were asked about being present at the convention that was held in Denver?

Mr. McCabe. Yes.

Mr. Davis. When was that Denver convention held?

Mr. McCabe. Sometime in the summer of 1909.

Mr. Davis. Do you remember the month?

Mr. McCabe. I do not. It was either July or August.

Mr. Davis. It was August, I believe; I am so informed. You attended that in your capacity as a member of the Board of Food and Drug Inspection?

Mr. McCabe. I attended it because in my capacity as an employee of the Department of Agriculture I was directed by the Secretary to go there.

Mr. Davis. Do you know how you gained admission to the floor to participate in the voting or debates; was it as a member of the force of the Secretary of Agriculture, or as connected with the Bureau of Chemistry?

Mr. McCabe. As associated with the Secretary of Agriculture—with the Department of Agriculture.

Mr. Davis. And not in connection with the Bureau of Chemistry?

Mr. McCabe. I never considered that I have been connected with the Bureau of Chemistry.

Mr. Davis. You voted in that convention?

Mr McCabe. I did; that is, I cast the vote of the Department.

Mr. Davis. Who constituted the representatives of the department whose conclusion was expressed in the vote that you cast?

Mr. McCabe. I think all the representatives of the department who were there.

Mr. Davis. I take that for granted; but were they connected with one or another bureau or branch of the department?

Mr McCabe. Connected with different bureaus and branches.

Mr. Davis. Could you enumerate them?

Mr. McCabe. Well, there was the Secretary's office; there was the Bureau of Animal Industry; and there was the Bureau of Chemistry.

Mr. Davis. And there were how many—nine, were there not?

Mr. McCabe. Nine what?

Mr. Davis. Nine representatives of the department.

Mr. McCabe. There must have been more than that, because there were, I think, five members of the referee board and the Chief of the Bureau of Chemistry. I remember Dr. Bigelow was there, although I think he was attending the meeting of official agricultural chemists. There was Dr. Kebler, Dr. Melvin, and I think Dr. Dorsett was there. That is simply from recollection. I think, perhaps, Dr. Rawl of the Dairy Division was there. I was there.

Mr. Davis. Before you went to that convention you took a trip through the Northwest, did you not, in connection with it?

Mr. McCabe. No; not in connection with it.

Mr. Davis. When did you leave Washington to go to the convention?

Mr. McCabe. I don't know.

Mr. Davis. How many days before the convention?

Mr. McCabe. Several days.

Mr. Davis. Do you mind saying where you went?

Mr. McCabe. I went directly from Washington to Denver.

Mr. Davis. Before that, had you been out in the Northwest at all on this business?

Mr. McCabe. Not on this business.

Mr. Davis. You had not been out there?

Mr. McCabe. I could not answer positively from recollection. I think I had taken an official trip before that time.

Mr. Davis. Was it not almost immediately before that?

Mr. McCabe. How long before, I don't know.

Mr. Davis. I wish you would look that up.

Mr. McCabe. I will verify that and put it in my testimony.

Mr. Davis. Would you object to stating what that trip was about?

Mr. McCabe. I would, from memory, because it has been a good while ago, and I do not remember about it.

Mr. Davis. Will you be good enough to refresh your recollection?

Mr. McCabe. Yes.

Mr. Davis. You were traveling at the expense of the Agricultural Department?

Mr. McCabe. Yes; it was an official trip.

Mr. Davis. And during that official trip, is it not a fact that you interested yourself to interview various persons who would be in attendance at that Denver meeting?

Mr. McCabe. I think I did.

Mr. Davis. With a view to the question that would come up in reference to benzoate of soda?

Mr. McCabe. With a view of upholding a ruling of the department.

Mr. Davis. Do you remember how many persons you interviewed during that official trip who afterwards appeared at Denver and voted to support the benzoate of soda decision?

Mr. McCabe. No.

Mr. Davis. Could you approximate the number?

Mr. McCabe. I do not know that I could. I would say possibly three or four or five.

Mr. Davis. In refreshing your recollection about the other matter, you can refresh your recollection about that and recall, if you can, the itinerary of your trip?

Mr. McCabe. Yes.

Mr. Davis. Be good enough to tell us who the persons were that you interviewed on that trip.

Mr. McCabe. I can tell you now that I interviewed every man I met that would probably come to the convention, and I asked every man of that kind I met to uphold the department when he got there.

Mr. Davis. And that you did while traveling on an official trip at the expense of the Department?

Mr. McCabe. Yes.

Mr. Davis. The exact object of that trip was what? Do you now remember?

Mr. McCabe. No; nor do I think it is remarkable that I do not remember.

Mr. Davis. I do not make any suggestion that it is remarkable.

Mr. Higgins. What is the purpose of this examination?

Mr. Davis. It is completed, Mr. Higgins. The purpose of it, I can say without the slightest reservation, is to show that the Solicitor for the Department of Agriculture was on a trip at the government's expense, if not for the purpose; with the effect of marshaling forces that were to be at the Denver convention to support the referee board's decision on the benzoate of soda question as against the decision of the Bureau of Chemistry on the same question.

Mr. Higgins. And he has stated that he did that at the request of his chief.

Mr. Davis. No; he has not stated that he did that at the request of his chief.

Mr. Higgins. I so understand—that he attended the Denver convention at the request of the Secretary of Agriculture.

Mr. Davis. Yes: but this was before this trip about which I have been inquiring.

Mr. Higgins. I would suggest that inasmuch as he said that, that it might be more pertinent to examine the Secretary of Agriculture when he comes on the stand.

Mr. Floyd. I think you misunderstand Mr. McCabe. He stated that it is true that he went to the Denver convention at the request of the Secretary of Agriculture; but Mr. Davis has been asking him about another trip he made.

Mr. Higgins. He stated, as I understand, that before that time he took an official trip, which, I presume, presupposes that the Secretary of Agriculture either directed him to make that trip or agreed that he should take it.

Mr. Floyd. He has been asked to refresh his memory about the details of that trip.

Mr. McCabe. I can state now with the greatest positiveness that if I met anybody on that trip, and I know I did meet some, who were entitled to go to that convention, that I asked them to go and when they got there to support the ruling of the Department of Agriculture; that I considered the investigation that had been made by the referee board and its adoption of the three Secretaries settled the question, and I hoped that we would not have a repetition of what occurred at Mackinac. I further argued with the men I met that when we got there we ought to have an open meeting and settle the question, and I worked, and worked hard, along that line, and I am very proud of it.

Mr. Higgins. At that time there was a great deal of contention among the food manufacturers, or certain food manufacturers, as to the use or harmful effect of benzoate of soda.

Mr. McCabe. From the moment the referee board was created there was a newspaper war carried on against that board——

Mr. Higgins. And is now, is there not?

Mr. McCabe. Well, the papers speak for themselves. There was a correspondent here in Washington almost from the time that the board was created who sent out any number of copies of articles reproduced by a typewritten process abusing the Secretary, abusing the referee board, impugning the motives of the Secretary for creating the board, attacking the personnel of the referee board; and those articles have continued to be sent out up to within certainly a very few days. The fight on benzoate of soda, so far as the manufacturer is concerned, was purely a trade fight. It was a matter of advertising. And when we got to Denver both sides were drawn up—the people who were opposed to benzoate of soda and opposed to the methods of the board and favored the findings of the Bureau of Chemistry.

Mr. Higgins. What people were principally opposed?

Mr. McCabe. The people who appeared there were the Heinz people, their advertising people, the people who have since formed an association of which Heinz & Co. and other manufacturers are members.

Mr. Higgins. What is the name of that?

Mr. McCabe. It is called the Association for the Promotion of Purity in Food Products.

Mr. Higgins. And where located?

Mr. McCabe. I think possibly their office is in New York, although I do not know. A representative of the national food magazine, *What to Eat*, the editor or proprietor of that paper, it was—I have never had any experience in attending many political conventions, but it was a stand-up and knock-down fight from the minute we got there until it was over, with both sides trying to control just as many delegates as they possibly could.

Mr. Floyd. How did the vote stand on the final vote?

Mr. McCabe. The vote on benzoate of soda, on the division, on the resolution indorsing the findings of the referee board—I do not know how it stood. The fight was continued—each side had a slate of officers. When the meeting was held at Mackinac behind closed doors, the result was that resolutions were published accusing and condemning the Secretary of Agriculture; and there was just one gentleman who had red blood enough to get up and say that he thought it was wrong for the Secretary of Agriculture to be condemned without a hearing.

Mr. Floyd. What I wanted to know was how the vote stood——

Mr. McCabe. That man was Mr. Flanders, of New York. I am coming to an answer to your question. I do not know how the votes stood on the question of benzoate of soda, but the result was an indorsement of the ruling of the department. We supported Mr. Flanders for president, and he won by one vote. The State of Georgia switched after the vote on president, I think—yes; I think it was the State of Georgia—and the rest of the other slate was elected.

Mr. Floyd. Now, right in that connection, before we get away from it, you stated that quite a number of the employees of the Agricultural Department and its different bureaus were there in addition to yourself.

Mr. McCabe. Yes.

Mr. Floyd. To get to the item of expense, were the expenses of these various employees paid by the Department?

Mr. McCabe. Yes; they always have been at every meeting.

[Dr. Robison, a chemist, attended the Denver meeting as a representative of the State of Michigan and voted for the commissioner of that state for president. He was also chairman of a committee on benzoate of soda. Later he testified for the State of Indiana in the Indianapolis case. For these offenses he was dismissed by Secretary Wilson.]

DR. ROBISON'S TESTIMONY

Mr. Moss. State your full name.

Dr. Robison. Dr. Floyd W. Robison.

Mr. Moss. What is your occupation or for what have you been fitted by occupation.

Dr. Robison. I am a chemist by occupation.

Mr. Moss. What official positions have you held?

Dr. Robison. I have held the official position of state chemist for the Michigan State Experiment Station and the position of state analyst of the Michigan State dairy and food department, and the position of a per diem employee, food and drug inspection, in the United States Department of Agriculture.

Mr. Moss. How did you obtain that employment in the United States Department of Agriculture?

Dr. Robison. Shortly following the passage of the national food and drugs act, by virtue of an examination taken under the Civil Service Commission, being duly certified by that commission and subsequently appointed over the official signature of the Secretary of the United States Department of Agriculture.

Mr. Moss Then you were a civil-service employee?

Mr Robison. Yes.

Mr. Moss. When did your connection with the Department of Agriculture begin?

Mr. Robison. I have the original appointment here which will answer that question.

Mr. Moss. You can refer to that.

Dr. Robison. My probationary appointment for a period of six months was made on May 1, 1907, which was followed on March 14, 1908, by a permanent appointment which was to take effect on November 9 the year previous, 1907.

Mr. Moss. When did your connection with the Agricultural Department terminate, if it has terminated?

Dr. Robison. My connection terminated on June 30, 1911.

Mr. Moss. How did it terminate—by resignation?

Dr. Robison. No, sir.

Mr. Moss. How?

Dr. Robison. By virtue of a letter of dismissal from the Secretary of Agriculture.

Mr. Moss. Were there any charges filed against you?

Dr. Robison. None.

Mr. Moss. Have you the letter of dismissal with you?

Dr. Robison. I have.

Mr. Moss. Please read it to the committee, so it will be a part of the record.

Dr. Robison (reading):

UNITED STATES DEPARTMENT OF AGRICULTURE,
OFFICE OF THE SECRETARY,

Washington, D. C., June 26, 1911.

Mr. Floyd W. Robison, of the State of Michigan, a food and drug inspection chemist, having a salary at the rate of $7 per diem when actually employed on the miscellaneous roll, paid from the fund appropriated for general expenses, Bureau of Chemistry, food and drugs act, salaries out of Washington in the Bureau of Chemistry, of the United States Department of Agriculture, is hereby removed from that position and his name ordered to be dropped from the rolls of the Department of Agriculture at the termination of June 30, 1911, and this order shall take effect on that date. He is removed from the department for the good of the service.

[SEAL] JAMES WILSON,
Secretary of Agriculture.

Mr. Moss. I will ask you if you have had any subsequent correspondence with the Secretary of Agriculture about this?

Dr. Robison. I have.

Mr. Moss. You will read the letter addressed to you by Secretary Wilson giving a more extended reason for your dismissal.

Dr. Robison. I will say, if the chairman will permit me, that following the receipt of that letter of dismissal I wrote a letter to the Secretary of Agriculture, a brief letter, in which I demanded of him by virtue of my right as an American citizen and as an employee under the civil-service act that he state the charges on file against me, and to that I received this letter.

Mr. Moss. You can place the copy of the letter in the record.

Dr. Robison. The letter I wrote him is in the hands of the Secretary of Agriculture.

Mr. Moss. Well, we may be able to get that. You may read the response of the Secretary of Agriculture to you.

Dr. Robison. This is dated, "Office of the Secretary of Agriculture. July 25, 1911:"

Mr. Floyd W. Robison,
1111 Union Trust Building, Detroit, Mich.

Sir: I have your lettter of July 14. The facts in the case are as follows:

In May, 1907, you were appointed food and drug inspection chemist, at $7 per day, on the food and drugs roll when actually employed. On November 9, 1908, you were transferred to the roll for food and drugs outside of Washington, D. C. During the year 1909 you were paid $28 and reimbursed $26.84 for expenses.

At the meeting of the Association of State and National Food and Dairy Departments at Denver in July, 1909, you attracted attention by taking a strong and public position against the policies of this department and of the administration. You appeared in the Federal court in Indianapolis in opposition to the policies of the administration with regard to the reports of the referee board on benzoate of soda and the report of the three secretaries with regard to it.

It recently came to my attention that beginning with February, 1911, you had resumed work under your old appointment, though you had not rendered any previous service since April 30, 1909. I had supposed that your long absence and work for the State of Michigan and positive stand against the administration had all resulted in your leaving the service. I have approved your dismissal for the good of the service. There are no charges against you; we make none. I recognize the fact that you have a perfect right to occupy any position you see fit with regard to the policies of the administration or of the department, but I do not think you should draw salary while you are taking this stand.

This is all I have to say. If you want a hearing, you can have one at any time.

Respectfully, James Wilson.

Mr. Moss. Were you a delegate to the Denver convention?

Dr. Robison. I was.

Mr. Moss. Whom did you represent at the Denver convention?

Dr. Robison. I represented the State of Michigan.

Mr. Moss. Who paid your expenses for attending that convention?

Dr. Robison. The State of Michigan.

Mr. Moss. Were you drawing any salary from the Government at the time you were at the Denver convention?

Dr. Robison. I was not.

Mr. Moss. Did you draw any money, either directly or indirectly, from the National Government for your attendance at the convention or for your expenses?

Dr. Robison. I did not.

Mr. Moss. What position did you hold at the Denver convention, so far as the convention itself was concerned?

Dr. Robison. I held the position of chairman of the committee of eleven state food chemists appointed by the president of the Association of State and National Food and Dairy Departments.

Mr. Moss. Did you make any report at that convention?

Dr. Robison. As chairman of the committee, I did, sir.

Mr. Moss. Will you read into the record just the report that you made to the convention?

Dr. Robison. I have this report embodied in my reply to the Secretary of Agriculture. I will state, Mr. Chairman, that the report involves several paragraphs, but the final recommendation of the report is the one——

Mr. Moss. Read the recommendation, and if the committee wants the entire report it can be inserted.

Dr. Robison (reading):

> Your committee therefore respectfully suggests to this association the wisdom of asking the President of the United States and the honorable Secretary of Agriculture to institute investigations along some such broader lines as indicated above.

Mr. Moss. In making that report did you make it in your personal capacity as the delegate or did you make it in your capacity as chairman of this committee?

Dr. Robison. I made it in my official capacity as chairman of this committee

Mr. Moss. As I understand it, you were appointed a delegate by the State of Michigan?

Dr. Robison. That is correct.

Mr. Moss. And expenses paid by the State of Michigan?

Dr. Robison. That is correct.

Mr. Moss. And as such delegate you were appointed chairman of the committee by the president of the association?

Dr. Robison. That is correct.

Mr. Moss. And as chairman you made a report of the convention?

Dr. Robison. That is correct, sir.

Mr. Moss. What disposition was made of this report?

Dr. Robison. The report was unanimously adopted by the convention.

Mr. Moss. Were you acting in any way, directly or indirectly, for the Department of Agriculture at the Denver convention?

Dr. Robison. I was not.

Mr. Moss. Did you receive any information from Secretary Wilson or any person representing the Department of Agriculture as to what the policy of the department or administration was?

Dr. Robison. I received no information from the Department of Agriculture or anyone else as to what the policy of the administration was.

Mr. Moss. Did you address the convention?

Dr. Robison. As chairman of this committee; yes.

Mr. Moss. I mean did you make an address there advocating benzoate of soda or opposing it in any way?

Dr. Robison. I did not.

Mr. Moss. Did you make any address to the Denver convention in which you referred to the Remsen board one way or the other?

Dr. Robison. I did not.

Mr. Moss. In your capacity as delegate did you cast a vote for president of that association?

Dr. Robison. I did.

Mr. Moss. Will you state for whom you cast that vote?

Dr. Robison. I cast that vote for the commissioner of the State of Michigan, who was a candidate for the presidency at that meeting.

Mr. Moss. Was the candidate for whom you cast your vote receiving the support of the Department of Agriculture at that convention?

Dr. Robison. He was not.

Mr. Moss. So far as you know, then, did you appear in opposition to the Department of Agriculture in any other manner except casting your personal vote for the president of the association?

Dr. Robison. I did not.

Mr. Moss. And will you state upon what grounds you cast your vote for the president?

Dr. Robison. On the grounds that the commissioner of the State of Michigan was a candidate for the presidency, and as a delegate of the State of Michigan I thought it my duty to cast the vote of Michigan for him.

Mr. Moss. So you cast it, then, upon the ground of state pride and your acquaintance——

Dr. Robison. Solely, sir.

Mr. Moss. At whose request did you appear at Indianapolis to give testimony at that trial?

Dr. Robison. At the request of the Board of Health of the State of Indiana.

Mr. Moss. Who paid your expenses at that trial?

Dr. Robison. The Board of Health of the State of Indiana.

Mr. Moss. Were you paid any fee?

Dr. Robison. I received no fee; no, sir.

Mr. Moss. At the trial in Indiana, upon what grounds did you testify? Upon the ground that you had done original work along the lines involved in the suit, and was testifying as to your own findings as the chemist of the original work?

Dr. Robison. Solely, sir.

Mr. Moss. In your testimony, then, were you testifying to discredit the policies of the administration or were you testifying as to the truth, as you understood it, of the issues involved, as discovered by your original work as a chemist?

Dr. Robison. I testified according to the truth as I understood it to be and had found it from my own investigations, and according to my oath, and without any regard in any capacity to any other policy.

Mr. Moss. Were you warned, either directly or indirectly, by any member connected with the Department of Agriculture, that you should not give this testimony, because it would be in opposition to the policies of the administration of the United States?

Dr. Robison. I was not.

[Dr. Wiley, although chief of the Bureau of Chemistry and responsible for the enforcement of the national Food and Drugs Act, was not a delegate from the Department of Agriculture and had no vote. Instead the delegation representing the pure food work of the national government was headed by Solicitor McCabe, a lawyer, who knows nothing of chemistry, foods or drugs. A portion of Dr. Wiley's testimony relating to the Denver meeting follows:]

DR. WILEY'S TESTIMONY

Mr. Davis. It was stated by Mr. McCabe, on page 436 of the record, that you, among others, attended the meeting at Denver which has been several times referred to in these proceedings. What is the fact about that?

Dr. Wiley. I understand that Mr. McCabe said I was a delegate.

Mr. Davis. That is the implication of his answer.

Dr. Wiley. I was not a delegate to the meeting at Denver. I went out there to attend a meeting of Official Agricultural Chemists, of which I am the permanent secretary, and also to visit my laboratory, or, I should say, the laboratory of the Bureau of Chemistry there, which I had never seen. During my stay there I was incidentally in the meeting of food commissioners a few times, and my name was down to read a paper on the program, and when the time came for my paper I was attending the meeting of the Official Agricultural Chemists, which was held in the same building, and the Secretary of Agriculture was appointed chairman of a committee to wait on me and bring me into the hall to read my paper. The Secretary of Agriculture and the committee waited on me and I went with them into the meeting, and the Secretary presented me to the chairman in a short speech and I read my paper, which consumed about 15 minutes, I think, and I then returned to the meeting of Official Agricultural Chemists. I was not otherwise a delegate to that convention and took no part whatever in its proceedings.

The Chairman. Did you vote in the meeting that you have been referring to—the meeting of the State and National Dairy and Food Department?

Dr. Wiley. No. When it came time for the Agricultural Department to vote Mr. McCabe asked me if I wanted to vote. I said, "No, I am not a delegate and I will not vote."

The Chairman. Were you paid any expenses for having attended the National Food and Dairy Department meeting?

Dr. Wiley. No. My expenses were paid to the other meeting, the Association of Official Agricultural Chemists, and the inspection of my laboratory. Nothing was paid in connection with the dairy and food commissioners.

Mr. Higgins. But you took the trip and this was incidental to your trip and the expenses for the trip were paid by the Department?

Dr. Wiley. Yes, sir.

Mr. Davis. You have spoken of the expenses of certain appointees as having been paid from the bureau, or some reference was made to that—in fact, I don't think you yourself have made a statement about it—and I call your attention to the names of Charles W. Boyle and others whom I named to Mr. McCabe, and Mr. McCabe stated that these persons had been appointed for duty in his office. I will ask you from what appropriation they were paid, if you know?

Dr. Wiley. I do know.

Mr. Davis. Well?

Dr. Wiley. They were paid from the money appropriated to the Bureau of Chemistry.

Mr. Davis. Did you ever have the services of those men or any of them?

Dr. Wiley. They were never in my office; not one of them to my knowledge.

Mr. Davis. In other words, they were appointed and they were paid out of your fund and they performed their duties in the office of the Solicitor?

Dr. Wiley. That is correct.

Mr. Floyd. Have you a list of those?

Dr. Wiley. I have. It is there [indicating].

Mr. Davis. I now hand you a list and ask you to examine this list and state whether that correctly gives the names and the compensation of the persons of whom I have just inquired?

Dr. Wiley (after examination of list). To the best of my knowledge and recollection it does. These appointments were made, and the only knowledge I had of them was that they had been appointed to the Bureau of Chemistry and detailed to the Solicitor's office, and that the money would be charged against the Bureau of Chemistry. That was to notify me so that I would not myself spend that money when it was being spent in another place.

Mr. Higgins. Did you understand that was for the enforcement of the Food and Drugs Act.

Dr. Wiley. I did not understand what it was for.

[Comment is hardly necessary on the portion of Secretary Wilson's evidence given below. Those who have followed the testimony of this case to this point will find a number of suggestive statements in the secretary's replies.]

SECRETARY WILSON'S TESTIMONY

The Chairman. It was at your request, Mr. Secretary, that certain employees of the Department of Agriculture attended the Denver convention of the Association of State and National Food and Drug Departments, was it not?

Secretary Wilson. Yes; that is right.

The Chairman. Did you assign any special duty to those employees who attended this convention, which duty did not appear on the published program of the association?

Secretary Wilson. That particular question I would have to look over my orders to refresh my recollection about. I do not remember anything of that kind, and yet it might have been.

The Chairman. Dr. Dunlap stated in his testimony before the committee that at your request he made an unofficial trip at public expense to confer with Dr. Remsen concerning the Denver convention. Will you be willing to explain to the committee what request you submitted to Dr. Remsen through Dr. Dunlap?

Secretary Wilson. I could not remember. If I can dig it up in my recollection or from any contemporaneous fact, I will be glad to send you an intelligent answer.

The Chairman. In a letter which Dr. Remsen wrote to you, Mr. Secretary, he used this language—and I can put in the entire letter, if you would like to have your recollection refreshed—in which he speaks of your plan as an excellent one. I will read it so it will come back to your memory and refresh your memory on the point.

The letter is dated June 30, 1909, and is as follows:

> MY DEAR MR SECRETARY: Mr. Dunlap has no doubt informed you of the general trend of our conversation. I have now to say that I have written to all the other members of the board urging them to arrange so as to be in Denver at the time of the meeting of the association. You may count upon the attendance of most of us. There is some doubt as to Dr Herter, as he has been somewhat disabled, but I know he will go if possible.
>
> Your plan, as explained by Dr. Dunlap, is an excellent one. It is time something definite were done. You will find our board not only willing, but anxious to cooperate with you in this effort to get things on a solid, scientific, common-sense basis.

The letter is addressed to you, Mr. Secretary, and is signed Ira Remsen, chairman of the Referee Board of Consulting Scientific Experts.

Secretary Wilson. Yes.

The Chairman. Would you care to explain to the committee what your plan was that you had Dr. Dunlap explain to Dr. Remsen?

Secretary Wilson. Surely. That was the Board of Foods and Drugs, and if I remember the names of those connected with it, nearly all of them have my permission to cooperate with us in their states, and so forth, and to help us, and we help them. They had met at Mackinac Island. I think it was, Lake Superior, if my geography does not desert me, and they had done queer things there. We had a referee board, and I think a pretty expensive referee board, you will confess. We had gone after big men, and it was costing a good deal of money, and those people met there at Mackinac Island and got themselves outside of sympathy with the department along those lines, attacked me personally, misrepresented things, and I thought the amount of effort the United States was making and the amount of money it was expending to get facts from the greatest chemists in the land made it worth while for us to get those big men there before that class of men and let them see them and let them hear them. I did not think they comprehended the difference there was between a small chemist and a big one. That was the one thing in my mind. They were in California studying the drying of foods with sulphur, that we spoke about this morning, and the arrangement was they should stop over at Denver on the way back. I was going to the forests, and I arranged and it was my plan to stop there on my way to the forests. I went into the forests from Denver and stayed a month. Those were the plans. There is nothing

I care to conceal here, not a thing. Those were the plans and we talked them over, and every one of them addressed that convention, every one of them, and I think those people got new light from those men.

The Chairman. However, I believe the function of the board was simply to make recommendations to you as Secretary of Agriculture, was it not?

Secretary Wilson. That was a function, of course; that was the original function; but they were on their way back, and they stopped over there and let them have the benefit of their high intelligence along those lines.

The Chairman. Do you consider, or did you consider at the time, that the attendance of members of the Remsen Board and Solicitor McCabe at this Denver convention, which we were speaking about heretofore, was in line with their official duties?

Secretary Wilson. Yes; it was a kind of public trial we were having really, of the Remsen board.

The Chairman. Their attendance being in the line of their official duty. Will you explain why you issued to each one of them a special authorization for traveling expenses to attend this particular convention, when each one of them had an annual authorization for travel anywhere in the United States upon official business?

Secretary Wilson. If you have evidence of that special authorization, you had better call my attention to it.

The Chairman. Very well, I will be glad to do that.

Secretary Wilson. I do not remember anything about that.

The Chairman. I have the special authorization for Mr. McCabe, which does not appear in our proceedings, but which was furnished by your kindness and your direction.

Secretary Wilson. There is not a thing we have that you can not get.

The Chairman. Probably I had better refresh your memory with that official authorization before making further inquiry about it. It is as follows:

> Washington, D. C., *July 1, 1909.*
>
> Dr. Ira Remsen,
> *Consulting Scientific Expert to the Secretary of Agriculture.*
>
> Sir: Authority is hereby granted you to perform such travel within and throughout the United States during the year 1910 as may be necessary in connection with your duties as consulting scientific expert. This authority may be extended by you to your associates, Dr. John H. Long, Dr. Russell H. Chittenden, Dr. Alonzo E. Taylor, Dr. C. A. Herter, associate consulting scientific experts, and to such regularly appointed assistants of the board as you deem proper. You, your associates, and the regularly appointed assistants mentioned above, will be allowed the usual traveling expenses when traveling upon official business.

In another communication you say:

> Washington, D. C., *August 6, 1909*
>
> Dr. Ira Remsen,
> *Consulting Scientific Expert to the Secretary of Agriculture.*
> *Johns Hopkins University, Baltimore, Md.*
>
> Sir: You are advised that authorization No. 1163, which permits you and the other members of the referee board to perform travel within and throughout the United States in connection with your duties as consulting scientific experts, is hereby so amended as to permit you and your assistants to attend the convention of the Association of State and National Food and Dairy Departments, to be held at Denver, Colo., beginning August 23, 1909, and I trust that you and your assistants will be able to attend that meeting while en route to or from the Pacific coast.

Secretary Wilson. I guess that is correct. What do you want to know about it?

The Chairman. I want to know, if this attendance was in line with their official duties, as stated here, why it was necessary they should have special authorization when they had a regular authorization?

Secretary Wilson. I presume they had some doubts about stopping off at Denver being in their original authorization. If they had, then I gave them all the authorization they would need.

The Chairman. If there were any doubt it would be doubt as to whether or not that came within their official duties?

Secretary Wilson. Precisely.

The Chairman. Do you hold that you have executive authority to add to the official duties of the Remsen board other than that prescribed in the order creating them?

Secretary Wilson. To this extent; yes.

The Chairman. To that extent you have?

Secretary Wilson. Yes.

The Chairman. I presume the same reply would be applicable as to the special authorization issued to Mr. McCabe?

Secretary Wilson. The same thing, although I do not remember now what authorization it was.

The Chairman. I will say to you, if you care to go into it, that I have a copy of the special authorization. It has been sent to me, but I presume it is not necessary to produce it at this point.

Secretary Wilson. Not at all; I take your word for it.

The Chairman. Do you consider there is any degree of doubt about Solicitor McCabe having the right and official duty to attend that particular convention any more than did the Remsen board?

Secretary Wilson. I do not imagine there would be much difference.

The Chairman. Was Mr. McCabe placed upon the program at that meeting, so far as you remember?

Secretary Wilson. That I do not remember.

The Chairman. Do you remember whether or not he was invited to address the convention?

Secretary Wilson. That I do not remember, either.

The Chairman. Do you remember whether any request came from that association officially to Mr. McCabe to attend that meeting or not?

Secretary Wilson. That I do not remember, either.

The Chairman. You stated there did such a request come to members of the Remsen board?

Secretary Wilson. Oh, yes; there is no question about that.

The Chairman. Would you mind, Mr. Secretary, looking up that question and placing in the record a statement as to whether or not there was a request came from the association to Mr. McCabe to attend?

Secretary Wilson. I will be glad to do it.

The Chairman. We will be glad if you will do that.

Secretary Wilson. I will be glad to do it, Mr. Chairman.

(Note.—On revising this testimony, Secretary Wilson finds, upon inquiry, that Mr. McCabe attended this convention at Denver as a delegate from the Department of Agriculture.)

The Chairman. In your letter of July 25, 1911—and I have the letter, if you care to refer to it—to Floyd W. Robison, in giving the reasons for his dismissal from public service, you stated that Dr. Robison attracted attention by taking a strong and public position at the Denver convention against the policy of your department and of the administration. I believe at that time Dr. Robison was a member of the Department of Agriculture, was he not?

Secretary Wilson. Dr. Robison's position in the Department of Agriculture at that time, I think, was a little bit peculiar. Dr. Robison was recommended to me by, I think, Dr. Wiley or some of the chemists, to be employed as expert to do some day's work; that is all—just some day's work, at so much a day. He did a few days' work and then he went and associated himself for two years with the Michigan people as their agricultural chemist, and I supposed he was out altogether, and so I did not pay any attention to his activities at Denver. But he was also active at other places. As I understand it, there is quite a difference between chiefs and subordinates of that kind. I learned, however, that he had been set at work again; that he had been in your State, Mr. Chairman, and had been active there. When you start out to drive a six-horse team, Mr. Chairman, if each horse is going to pull his own way, you will never get anywhere. I do not propose to have subordinates in my department going off on tangents that are against the decisions of the three secretaries and myself, and all that, after we have gone to the expense of hiring such noted experts and scientists as we did to make up that referee board. I propose the gentlemen will work in line or keep still about it.

The Chairman. That particular phase was covered in full in Dr. Robison's testimony, and I want to get your version of it. In what particular way, Mr. Secretary, if you care to state it, did Dr. Robison oppose your policies at the Denver convention?

Secretary Wilson. Dr. Robison was not frank in that testimony before you. He did not say a word to you about his being away two years. He really did not belong to our department. But under that old appointment he had a few days' work which he was put on actively at New York, and I did not think it ought to be without my knowing it.

The Chairman. That is all right about that; but will you kindly explain again in what way at Denver he was opposed to your policy or to the policy of your department? In what particular thing did he oppose your policy? What particular thing did he do or what particular thing did he favor that was opposed to it?

Secretary Wilson. He was connected with a committee or board to get up resolutions, is my recollection.

The Chairman. He stated he appeared there as chairman of the board.

Secretary Wilson. Yes; appointed at this Mackinac Island meeting, I think.

The Chairman. Did you understand, Mr. Secretary, that his action in reporting there was a personal one, or that he was acting for the committee?

Secretary Wilson. If he belonged to the Department of Agriculture, he should have gotten consent from the Department of Agriculture to do that kind of work. The fact is, he did not.

The Chairman. You mean he should have gotten consent before he accepted the chairmanship of that board?

Secretary Wilson. Surely.

The Chairman. He should?

Secretary Wilson. He should have done so.

The Chairman. Was Dr. Robison there at the expense of the Department of Agriculture?

Secretary Wilson. No; he was not. And I do not think he belonged to the Department of Agriculture at that time. I think he belonged to the Michigan people.

The Chairman. The only opposition he could show was as being opposed to the decisions of the referee board in the matter of benzoate of soda. That is it, is it not?

Secretary Wilson. Precisely it. That was the dividing line.

The Chairman. You also stated that he appeared in the federal court in Indianapolis in opposition to the policies of the Department of Agriculture. Please explain in that regard.

Secretary Wilson. If he belonged to the Department of Agriculture, he should have consulted me before going anywhere to discuss or act with regard to that question. That is the position I took.

The Chairman. Is it not true that Dr. Robison is the only employee of the Department of Agriculture who appeared in Indianapolis and testified in behalf of the state in that suit?

Secretary Wilson. That I do not know.

The Chairman. Has any other employee who attended there for the State of Indiana been called to your attention as attending?

Secretary Wilson. I have no recollection.

The Chairman. Is it not also true that at least four of the employees of the Department of Agriculture did attend at Indianapolis and testified for the plaintiffs in that case?

Secretary Wilson. It has come to my attention that we paid the expenses of one, and I have heard incidentally that there were two others there. I never heard of the fourth.

The Chairman. I am making that statement of four upon the statement of the attorney, Mr. Baldwin. Up to that time I only knew of three who were members of the Remsen Board. I believe Mr. Baldwin stated there were four, one coming from Kentucky.

Secretary Wilson. I do not happen to know of anybody that would go there from Kentucky, but I do not think that is very important.

The Chairman. The records of your department would show that those employees of your Department of Agriculture who appeared at Indianapolis are still within the employ of the government, will they not?

Secretary Wilson. I think so, if they are.

The Chairman. And those records will also show that Dr. Robison was discharged?

Secretary Wilson. Oh, the records will show that, surely.

Correspondence

Informing the "Typhoid-Carrier"

To the Editor:—It has been found that 3 to 5 per cent. of the patients recovering from typhoid are "carriers," that is, have typhoid bacilli in their stools even after they are well enough to be up and about. These unfortunate individuals are a danger to those about them and constitute one of the most difficult problems in preventive medicine. Although physicians are well aware of these facts, very little is done to minimize this source of infection. Hospital patients and private patients are discharged from observation without an examination to discover which are the "carriers" and which are rid of typhoid bacilli. This *laissez-faire* attitude is probably due to the irksomeness of routine bacteriologic examinations, and to the realization that we are in possession of no means of curing a "carrier." Nevertheless, I believe that we are not justified in taking this position, in sending patients back to their homes in ignorance of the fact that they may readily transmit typhoid to their friends and relatives. Although it is true that we cannot rid them of typhoid bacilli, there would be a decided advantage in most cases if the individuals were aware of their infectious state. As things are now, they go home and take no precautions, many of the women cooking the meals or at least handling the food as usual. They do not know that they should observe especial cleanliness in the various sanitary matters which it is unnecessary to detail.

I feel that this state of affairs constitutes a very weak link in the chain of the prophylaxis of typhoid. It seems to me that it would not involve too great labor to have a bacteriologic examination made of the stools before each typhoid patient is discharged from the hospital. It would not be possible to detain the patient until a negative culture could be obtained, as we do in the case of diphtheria; however, we could inform the "carrier" (and possibly the board of health as well) of his condition, and give him written instructions as to the precautions which he should observe. We might even arrange for subsequent stool examinations by the hospital or by the board of health, so as to acquaint the patient when he is finally rid of the bacilli.

This subject was recently brought home to me with emphasis when, following the discharge from the hospital of two children who had been suffering from typhoid, a third case immediately developed in the home.

Alfred F. Hess, New York City.

The Home for Widows and Orphans of Physicians

To the Editor:—In a communication by me to The Journal of Aug. 28, 1909, page 735, regarding the "Fund for Relief of Widows and Orphans," founded by the Medical and Chirurgical Faculty of Maryland in 1903, I stated that it was our hope eventually to found here also a home where the widows and children needing it could be cared for, the children educated and helped to get a start in the world and even helpless or superannuated physicians could find a shelter. It was our purpose and desire that this work, like the fund, should be under the direction and control of the faculty, which is the state medical society. Unfortunately it was found that the charter of the society gave no authorization for the institution and the advice of lawyers who were consulted was against its assumption.

Believing thoroughly in the urgent need of a home and compelled to act independently, we set to work to raise funds. The result of our efforts so far—a little over a year—is a substantial fund in the bank, and we are now on the lookout for a suitable property within the city with a view to purchase. We propose to start within the city, where it will be convenient to our workers and in a modest fashion work up.

And now we appeal to the members of the medical profession throughout the United States for their aid. By its charter the home is to be one for the "widows and orphans of physicians" and this in no limited sense. The institution is national in scope and those for whom it is designed will be welcomed whether they come from the north or the south, the east or the west. Those worthy will be admitted without unnecessary delay and without admission fee. We hope to see it grow rapidly and to be able to accommodate all who need assistance. We ask contributions of all whose hearts can be touched by pity or suffering. We ask for the widows and orphans of our brethren. Who knows but that our own widows and orphans may some day need this very help?

Eugene F. Cordell, M.D., Treasurer.
257 W. Hoffman Street, Baltimore.

Factors in Death-Rate.—Hoffman, in his paper on the "General Death-Rate of Large American Cities," enumerates the following factors as affecting the rate: size of city, density of population, latitude, longitude, elevation, rate of annual increase, proportion of males, of foreign-born, of foreign parentage, of colored, of illiterate, of male wage-earners, of ages, the mean annual maximum and minimum temperature, and mean annual relative humidity; so that the general death-rate, when analyzed, is found to be based on a very complex set of props, and the influence of the most important must be measured before accepting it as an index of mortality.

Queries and Minor Notes

Anonymous Communications will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

LANOLIN NOT A PROPRIETARY

To the Editor:—In saying that "lanolin" is a "non-proprietary name" (The Journal, Sept. 9, 1911, p. 902), do you mean that it is neither trademarked, patented or in other ways protected? I should be pleased to know that.

Adolph Koenig, Pittsburgh.

Answer.—In the case of lanolin the supreme court of the State of New York upheld the principle that as the name given by the parent to the child belongs to the child, so the name applied to a product belongs to that product and not to those who gave the name. Therefore, the court ruled that the name used to designate a patented product becomes the proper designation of that product and that, when the patent expires, others may make and sell the product and may also apply the name originally used by the owners of the patented product. In the lanolin case it was held that anyone could manufacture the product and could call it lanolin so long as no attempt was made to mislead the buyer into believing that the particular product was made by the original patentees, when it was not.

BREEDING PLACES FOR FLIES AS NUISANCES—DISPOSAL OF WASTES IN A NON-SEWERED TOWN

To the Editor:—1. What sanitary regulations would you consider advisable and practicable in regard, particularly, to disposal of livery stable and other manure in a small, flat, river-valley town without sewers? 2. Suppose in the absence of adequate town or county regulations a citizen relied on a statutory prohibition of "nuisances," and prosecuted an offender, say a livery stable keeper, for depositing and accumulating manure in proximity to dwellings, what test might reasonably be applied in defining the term "nuisance"? Could such manure fairly be considered a "nuisance" after one day, or one week, or one month? 3. What time would be needed for the incubation of flies in such manure?

W. R. Tymms, Orting, Wash.

Answer.—1. It could not be considered an unreasonable sanitary regulation to require that stalls be cleaned daily and that stable manure be kept in closed, or at least carefully screened, bins to prevent access of flies, and that it be removed therefrom at least once a week. This would no doubt prevent the breeding of flies and would avoid any considerable accumulation of the manure and consequent nuisance. In addition, to prevent the breeding of flies, a regulation requiring the sprinkling of the daily accumulation with a solution of iron sulphate, one pound to the gallon of water, might be adopted. This is cheap and is said to be effective, and does not spoil the manure for fertilizing purposes. The manure when removed should not be deposited in heaps on the ground, particularly within the town limits, but should be immediately thinly spread. It will then dry out and will not afford a good breeding place for flies.

2. The Supreme Court of Washington has suggested that the question of nuisance or no nuisance cannot be determined by reference to the rules of the common law, but that each case must be considered on its own facts. The case of Everett *vs.* Paschall (111 Pac. R. 879) was briefly abstracted in the Medicolegal Department of The Journal, Jan. 28, 1911, p. 296, under the heading of "Private Tuberculosis Sanitariums As Nuisances." Other instructive comparatively recent decisions of that court on the general subject of nuisances are Thornton *vs.* Dow (111 Pac. R. 899), and Densmore *vs.* Evergreen Camp (112 Pac. R. 255). Coker *vs.* Birge (9 Ga. 425) is an old case holding a livery stable near a hotel to be a nuisance, while in Albany Christian Church *vs.* Wilborn (112 Ky. 507), a private stable near a church is held not necessarily to be a nuisance, everything depending on how it is kept.

3. According to observations by the Public Health Service the eggs of flies were hatched eight hours after being laid; Newstead of Liverpool found that in a temperature of from 75 to 80 F. they hatched in from eight to twelve hours; in a temperature of 60 F. in twelve hours, but at 45 F. they did not hatch until they were brought into a warmer atmosphere on the third day. The duration of the egg stage, as observed in Washington, was usually eight hours; that of the larval stage less than five days. The adult fly may emerge between the third and fourth day after pupation—making in all nine days from the laying of the egg to the appearance of the grown fly. Where the manure is in small piles, or is partly spread out, the full-grown larvæ almost ready for transformation are apt to migrate into the loose ground under the pile or from the edges of the pile outward, to transform under nearby rubbish. This habit may have a very important practical value, since municipal regulations of individual stable practice in regard to the removal of manure should take into consideration that such removal at intervals longer than those required for the larva to reach full growth may result in the leaving of many puparia, except, of course, in cases in which especial receptacles for manure are in use.

Literature on the subject was cited in this department June 24, 1911, p. 1900, and in the Miscellany Department Sept. 3, 1910, p. 875. The latter also refers to the disposal of human excreta. See also the Department of Book Notices, this issue, page 1079.

OPEN-AIR TREATMENT OF BURNS

To the Editor:—Please describe in brief the open-air treatment of burns.

C. L. Olson, McIntosh, S. Dak.

Answer.—The open-air treatment of burns was described in The Journal, Aug. 18, 1906, page 529, as follows: Concerning the local treatment of the burned area, the tendency at present is to the open-air method. The uncovered skin is left exposed to the air, blebs are removed, the area gently dried, dusted with stearate of zinc or other bland dusting powder, and fanned to hasten drying and the formation of crusts. Contrary to early ideas the pain under this line of treatment soon subsides and healing is more rapid than under moist dressings. The unburned portion of the surface should be bathed and cleansed often and the temperature of the room should be maintained high in order to favor the action of the skin. The air must be kept as pure as possible and the utmost cleanliness maintained about the bed linen and everything else that comes in contact with the patient. A liberal supply of pure water should be provided, and only liquid nourishment allowed until the dangers of intestinal complications have passed.

TEXT-BOOKS ON MATERIA MEDICA

To the Editor:—Is there any materia medica published which classifies and describes the medicines under their principal therapeutic action—*e. g., medicines acting on the heart, nervous system,* pulmonary system, etc.?

E. H. Sauvignet, Laredo, Tex.

Answer.—The principal text-books of materia medica classify drugs in one of four ways: 1, according to origin; 2, according to composition; 3, according to physiologic action; 4, alphabetically.

In the first class is Culbreth; in the second class, Phillips; in the third class, Bartholow, Butler, Cushny, Sollmann, Stevens, Wilcox, Wood; in the fourth, Hare, Potter and Shoemaker.

NO RECIPROCITY BETWEEN NEW YORK AND NEW JERSEY

To the Editor:—Does New Jersey have reciprocal relations in medical licensure with New York?

C. M. E.

Answer.—Reciprocal relations between New York and New Jersey were discontinued in 1910 and have not been resumed.

FORMULA FOR FELT OR CLOTH SPLINT

To the Editor:—In The Journal, Sept. 9, 1911, p. 918, F. S. B. asks for a formula for a good cloth or felt splint. He will find the following very useful;

One pound of gum shellac is dissolved in 1½ pints of alcohol with 1 dram of borax. This makes a thrick solution. In order to make the splints, the solution should be applied on one side of a woolen cloth with an ordinary paint brush and dried thoroughly; then a second coat is applied on the same side and dried as at first, making a single piece. If a stronger piece is needed the solution should be applied on the sides of two pieces that have already been saturated, and put together and pressed with a hot iron until they unite and become as one piece. Cloth that has been worn is better than new cloth, for it is more porous and takes up more of the solution. The alcohol should be evaporated out of the cloth before applying the second coat; also good shellac that has not been adulterated should be used. It will dissolve in a few moments if held in hot water. The splint can be tempered by holding before a hot fire till soft, then placing in a cold atmosphere or in cold water.

For dressing the limb, the splint should be immersed in hot water or held before a hot fire till soft; then applied and shaped to the limb; then removed and lined with some soft material, reappplied and bandaged.

A. E. Spalding, M.D., Luverne, Minn.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

ARIZONA: Phoenix, October 2-3. Sec., Dr. Ancil Martin.

COLORADO: The State Capitol, Denver, October 3. Sec., Dr. David A. Strickler, 612 Empire Building.

GEORGIA: Regular, Atlanta, October 10. Sec., Dr. C. T. Nolan, Marietta. Homeopathic, Atlanta, October 10. Sec., Dr. R E. Hinman, 106½ Whitehall Street.

IDAHO: Wallace, October 3-4. Sec., Dr. O. J. Allen, Bellevue.

ILLINOIS: Coliseum Annex, Chicago, October 26-28. Sec., Dr. J. A. Egan, Springfield.

LOUISIANA: New Orleans, October 19-21. Sec., Dr. A. B. Brown, 108 Baronne Street.

MICHIGAN: Legislative Bldg., Lansing, October 10-12. Sec., Dr. B. D. Harison, 504 Washington Arcade, Detroit.

MINNESOTA: State University, Minneapolis, October 3. Sec., Dr. W. S. Fullerton, St. Paul.

MISSISSIPPI: State Capitol, Jackson, October 10-11. Sec., Dr. S. H. McLean.

MISSOURI: Kansas City, September 25-27. Sec., Dr. Frank B. Hiller, Jefferson City.

MONTANA: The Capitol, Helena, October 3. Sec., Dr. W. C. Riddell.

NEW JERSEY: The State Capitol, Trenton, October 17-18. Sec., Dr. H. G. Norton, 429 E. State Street.

NEW MEXICO: The Capitol, Santa Fe, October 9-10. Sec., Dr. J. A. Massie.

OKLAHOMA: Muskogee, October 10. Sec., Dr. John W. Duke, Guthrie.

RHODE ISLAND: Room 315 State House, Providence, October 5-6. Sec., Dr. Gardner T. Swarts.

UTAH: Salt Lake City, October 2-3. Sec., Dr. G. F. Harding, 310 Templeton Building.

WYOMING: Riverton, October 9-11. Sec., Dr. A. B. Tonkin.

Pennsylvania June Reports

The Medical Council of Pennsylvania reports the written examinations held at Philadelphia, Pittsburgh and Harrisburg, June 27-30, 1911. The number of subjects examined in was 9; percentages required to pass, 75. At the examinations held by the State Medical Society of Pennsylvania, at Philadelphia and Pittsburgh, the total number of candidates examined was 377, of whom 359 passed and 18 failed. The following colleges were represented:

PASSED

College	Year Grad.	Total No. Examined.
Yale University	(1908)	1
Chicago College of Medicine and Surgery	(1911)	2
University of Louisville	(2, 1910) (3, 1911)	5
University of Maryland	(1909) (1910) (6, 1911)	8
Baltimore Medical College	(1908) (4, 1911)	5
College of Phys. and Surgs., Baltimore	(1908) (3, 1911)	4

The Public Service

Medical Corps, U. S. Navy

Changes during the week ended Sept. 16, 1911.

Wells, H., medical director, detached from command of the naval hospital, Portsmouth, N. H., and ordered home.

Higgins, S. L., P. A. surgeon, ordered to duty at the naval hospital, New York.

Huff, E. P., P. A. surgeon, detached from the Navy yard, Washington, D. C., and ordered to duty at the naval hospital, New York.

Porter, F. E., P. A. surgeon, ordered to the Navy yard and to additional duty at the naval hospital, Portsmouth, N. H.

Crow, G. B., asst. surg., ordered to duty at the naval hospital, Philadelphia.

Bogan, F. M., surgeon, detached from the *Wisconsin* and ordered to duty at the naval hospital, Portsmouth, N. H.

Rennie, W. H., P. A. surgeon, detached from the *Tacoma* and ordered to the *Wisconsin*.

U. S. Public Health and Marine-Hospital Service

Changes for the fourteen days ended Sept. 13, 1911.

Glennan, A. H., asst. surg.-gen., granted nine days' leave of absence from Sept. 7, 1911.

Cofer, L. E., asst. surg.-gen., granted ten days' leave of absence from Sept. 18, 1911.

Austin, H. W., surgeon, detailed to represent the Service at the annual meeting of the American Hospital Association to be held in New York City, Sept. 19-22, 1911.

Carter, H. R., surgeon, granted seven days' additional leave of absence from Aug. 31, 1911.

McIntosh, W. P., surgeon, leave of absence for fifteen days from Sept. 1, 1911, amended to read "fifteen days from Sept. 4."

Wertenbaker, C. P., and Young, G. B., surgeons, detailed to represent the Service at the next annual meeting of the Association of Military Surgeons, to be held at Milwaukee, Wis., Sept. 26-29, 1911.

Eager, J. M., surgeon, directed to proceed to Marseilles, France, for duty in the office of the American consulate.

Gardner, C. H., surgeon, granted ten days' leave of absence from Sept. 5, 1911, on account of sickness.

Foster, M. H., P. A. surgeon, directed to proceed to Stapleton, N. Y., and report to the medical officer in command for temporary duty and assignment to quarters.

Grimm, R. M., asst. surgeon, detailed to make an investigation of local outbreaks of pellagra.

Del Valle Atiles, Pedro, A. A. surgeon, granted thirty days' leave of absence from Sept. 1, 1911.

Duffy, Francis, A. A. surgeon, granted twenty days' leave of absence from Sept. 1, 1911.

Hembree, A. T., A. A. surgeon, granted fifteen days' leave of absence from Aug. 15, 1911.

Kaplan, Maurice L., A. A. surgeon, granted seven days' leave of absence from Aug. 15, 1911, under paragraph 210, Service Regulations.

Kennedy, S. R. M., A. A. surgeon, granted thirty days' leave of absence from Sept. 1, 1911.

Moorer, M. P., A. A. surgeon, granted fourteen days' leave of absence from Sept. 5, 1911.

Robinson, H. D., A. A. surgeon, granted seven days' leave of absence from Sept. 11, 1911.

Tarbell, B. C., A. A. surgeon, granted thirty days' leave of absence, with pay, from Aug. 21, 1911, and thirty days, without pay, from Sept. 20, 1911.

Clegg, Moses T., assistant director, Leprosy Investigation Station, leave of absence for twenty-eight days, with pay, from July 12, 1911, and two days, without pay, from Aug. 14, 1911, amended to read "twenty-six days, with pay, from July 12, 1911."

Stiles, C. W., professor of zoology, directed to represent the Service at the Conference on Hookworm Disease to be held in Nashville, Tenn., Sept. 14-16, 1911.

INFANT WELFARE IN LEIPSIC

By Charles R. Henderson, Ph.D., D.D.
Professor of Sociology in the University of Chicago
CHICAGO

The organization of Leipsic is selected as a concrete illustration of recent tendencies in German cities because it is relatively well developed and because it was early in the field. Its administrative measures cannot be slavishly copied, but they are suggestive for American cities, where lawyers, physicians and philanthropic workers are wisely joining forces.

In Leipsic the local court centralizes guardianship for all public wards in one city office, an arrangement which simplifies the judicial tasks and makes the guardianship more effective. This central office, with expert lawyers in charge, is responsible to the court for all illegitimate children in Leipsic from birth to the end of school age, whether in charge of the mother or of some other person. Legitimate children placed with foster parents at public cost are under the same supervision. The care is extended to majority.

Every birth is reported to the police office by the midwife or physician. Neglect of this important duty is punished. Then begins the activity of the physician for foster children, the man who was a pioneer in rational and effective methods, Dr. Taube. In the splendid new city hall, the medical staff have commodious quarters: office for inspections, large waiting-rooms, consultation and nursing rooms and even courts for baby carriages. The municipal authorities evidently appreciate the importance of infant welfare. The mother or foster mother must present the child soon after its birth, on Friday afternoon, in one of the places appointed. From the beginning, the child is under medical control. Dr. Taube has long insisted that "it should be legally forbidden for any one to assume charge of an infant in return for payment without knowledge of the central office." The direct supervision of the infants, after the examination by the physicians, is carried out by women assistants who are carefully selected, trained and paid. They receive at first $125 yearly and may be advanced to $300. Twenty-one days each year are given for vacation. From personal observation, from actual visits of inspection in the dwellings of the poor, and from authoritative information, I have received a very favorable impression of these supervising women. Each one of them is assigned about 285 to 300 children; for inspection the very young, the sick and the feeble are visited most frequently. The observations made and recorded, extend to rooms, beds, food, clothing and conduct of the foster parents. Cases of suspected communicable diseases are isolated. Sick children are treated by other city physicians at cost of the sickness insurance or poor relief funds.

Foster parents must be approved by the central office. In many places visited in the city the dwellings were defective and crowded, especially where poor, unmarried mothers are compelled to live. Here one realizes the close connection of housing reform and infant mortality, for without the sharp and competent inspection of the women assistants good results would be impossible. The foster parents are paid about $1.25 a week.

Another tour of inspection with Dr. Taube, revealed the inner workings of the system in the rural colonies when the central office places children until their fourteenth year, at which time they are apprenticed. Each colony has from fifty to sixty wards in as many foster homes, and is placed under the supervision of a resident who is generally the village pastor. This superintendent is not paid for his services, but for outlays he receives about $1.25 a year for each child. In addition to this, the places are constantly inspected by trained visitors and physicians. Medical services are paid by the city.

A children's home supplements the municipal activity and comes under the same medical control. This institution was founded in 1878 by benevolent individuals and is especially designed for unmarried mothers, frequently domestics, before and after their first confinement. The woman can come several weeks or months before confinement and must promise to remain six months to nurse the child and, perhaps, some motherless infant. The housework is done by the inmates. Nurslings thrown on the care of the city are temporarily kept here. The institution also trains children's nurses. In the year 1910, 325 children were cared for, with forty-four deaths (13.5 per cent.). On the day of my visit in August, 1911, there were 110 children.

Since the year 1906, nursing premiums have been given to those mothers to whom nursing the child would involve a loss of earnings, or who, from poverty, could not give the breast without assistance. The weekly allowance is from 75 cents to $1.50, paid out by a mature and married officer at a place appointed for consultations. These premiums are not counted as poor relief. In 1908, there were, 1,316 requests for this aid, and $6,000 are in the city budget for the purpose. One private society gives aid to married mothers at confinement, and another gives attention to legal protection.

Sick and indigent illegitimate nurslings and children of dependent mothers are given milk through contracts made with several milk dealers who are required to supply milk at 5 cents a quart, 3 per cent. fat content being required. Dr. Seiffert's laboratory controls the quality of this milk, and all milk is also subject to inspection by the health office. Milk depots do not exist, "because they are too dear, are invoked too late and have a tendency to hinder breast feeding." The mothers are taught to boil milk when nursing.

At the end of 1910, of the 9,323 children who were on the records of the municipal office, 7,443 were under this general guardianship.

The collection of money from fathers is a necessary factor in reducing infant mortality. In 1910, 2,213 fathers of illegitimate children paid over $90,000. Since the beginning of 1900 more than $500,000 have been thus contributed. Where mothers are working for wages they are automatically insured against sickness and the fund provides medical relief. If there is no insurance the city physician is called.

The reduction of mortality of illegitimate infants from 33.4 per cent. in 1904 to 21.05 per cent. in 1910 is substantial evidence that the new methods are efficient. The mortality from summer diarrhea is lower with the illegitimate than with the legitimate children, because of the closer supervision of the former. The number of atrophic children at the end of the nursing period has sensibly diminished.

Moral results cannot be tabulated. But it is believed by the authorities that the more complete enforcement of the law tends to make men more thoughtful.

The lesson for American cities is obvious. We need a central and trained guardianship for all children who require protection. In a central municipal authority should be coordinated all the medical, legal and educational public forces. Public and private charity should be auxiliary and cooperative. The details must be worked out by study and experiment. The Leipsic organization is rich in hope and instruction.

To City Councillor Dr. Weber and to Private Sanitary Councillor Dr. Taube I am deeply indebted for explanations, documents and opportunity of seeing at close range, through a prolonged stay, the many activities of their department.

POSTGRADUATE COURSE FOR COUNTY SOCIETIES

[Note.—The pamphlets containing the outline of the postgraduate study course for county societies for the coming year are ready for distribution. Secretaries of county societies can secure supplies by writing to the Secretary, Council on Health and Public Instruction, American Medical Association, 535 Dearborn Ave., Chicago.]

First Month—Third Weekly Meeting

Angioma

Simple Nevus: Varieties, structure of each, distribution.

Cavernous Nevus: Structure, distribution, prognosis.

Plexiform Angioma: Structure, distribution.

Lymphangioma

Lymphatic Nevus: Microscopic changes, distribution.

Cavernous Lymphangioma: Structure.

Lymphatic Cysts: Structure, occurrence, distribution, prognosis.

Sarcoma

General Characters of Sarcoma: Vascular supply, metastasis, capsule, infiltration, lymphatic supply, secondary changes, distribution.

Round-Celled Sarcoma: Microscopic section, distribution, age, prognosis.

Lymphosarcoma: Microscopic section, distribution, age, prognosis.

Spindle-Celled Sarcoma: Microscopic section, distribution, prognosis.

ALVEOLAR SARCOMA: Microscopic section, origin, distribution.

MELANOSARCOMA: Microscopic section, pigment, origin, distribution, prognosis.

CARCINOMA

ORIGIN, MICROSCOPIC STRUCTURE, VARIETIES

GLANDULAR CANCER: Distribution, gross and microscopic appearances, lymph- and blood-vessels, secondary changes, differentiate from adenoma.

SQUAMOUS-CELLED CANCER: Distribution, gross and microscopic appearances, characteristic margin, infiltration, secondary changes.

Book Notices

THE HOUSE-FLY, DISEASE-CARRIER. An Account of Its Dangerous Activities and of the Means of Destroying It. By L. O. Howard, Ph.D. Cloth. Price, $1.60 net. Pp. 312, with 35 illustrations. New York: Frederick A. Stokes Co., 1911.

This is not a scientific treatise but a book for the general reader. Nevertheless, it is accurate and complete from a scientific standpoint. Probably none of our American entomologists is better fitted to write such a book than Dr. Howard. His first publication on this subject was in 1896, when he contributed the chapter on the life-history of the fly to a bulletin on household insects published by the Department of Agriculture. In 1900, he published a long paper on the transmission of typhoid fever by flies. This volume can be commended to all who wish to learn the life history, personal habits, dangers and means of exterminating the common house-fly, the constant companion of man for centuries. Unfortunately, the character of the fly does not improve with acquaintance. His origin is not only lowly but filthy. He is prolific to an extent beyond the reach of ordinary figures. For instance, Dr. Howard estimates that one fly, survivor of a winter, laying 120 eggs on April 15 will, on September 10, be the direct ancestor of 5,598,720,000,000 adult flies, of which one-half will be females. This is the opposite of race suicide for the fly, but something very like race murder for its human associates. The book is well written, copiously and illuminatingly illustrated and well printed. It contains practically all the important facts available regarding the house-fly and is admirably adapted for popular use. An extensive bibliography is found in the appendix.

THE NATURE OF ENZYME ACTION. By W. M. Bayliss, D.Sc., F.R.S., Assistant Professor of Physiology, University College, London. Second Edition. Cloth. Price, $1.20 net. Pp. 137. New York: Longmans, Green & Co., 1911.

This volume of "Monographs on Biochemistry"—the first one to enter a second edition—covers adequately and accurately this interesting and fundamentally important subject. Presented originally in the form of lectures, it is more easy to read and assimilate than treatises of this sort are likely to be, a point of particular favor in the eyes of readers who are interested in the subject only in its general aspects. In the new edition the more recent contributions to enzyme chemistry and the theories of enzyme action have been incorporated, the author assuming the reasonably conservative attitude necessary in considering a subject in which theorization is so prominent.

DIE NEURALGIEN DER TÄGLICHEN PRAXIS. Von Dr. O. Schellong, Arzt in Königsberg i. Pr. Paper. Price, 1.80 marks. Pp. 83. Berlin: Julius Springer, 1911.

This is an instructive monograph on a very practical subject. The author bases his conclusions on an experience with 438 persons suffering from neuralgia among a clientele of 2,631 patients. He first gives a general study of the subject and follows this by a detailed consideration of the different forms of neuralgia as manifested in different nerves. A considerable number of case-reports are inserted and the treatment is succinctly described. A few synthetic remedies are given a place, but there appears to be no tendency to overestimate them.

Physical Examination of Female Plaintiff Required

(Illinois Central Railroad Co. vs Beeler (Ky.), 135 S. W. R. 305)

The Court of Appeals of Kentucky holds, in directing a new trial in this personal injury case, brought by the latter-named party, that a physical examination of the plaintiff *should be ordered, if asked for by the defendant.* It says that the plaintiff claimed that, as a result of her injuries, her monthly period was decreased to two weeks and she suffered from falling of the womb. An affidavit was filed, on behalf of the defendant, setting out the importance of having an examination made by some competent physician or surgeon, in order that the real condition of the plaintiff might be made to appear; and asked the court to appoint a physician and order that such an examination be made. The plaintiff objected, and filed affidavits to the effect that a medical examination could not be made to ascertain the extent of her injuries without offending decency and inflicting severe pain. No physician had made an examination to determine whether she in fact had the troubles claimed. Her family physician had only her word for it, but stated that he could easily determine by a physical examination whether the alleged troubles existed or not. In other words, here was a case where the injury complained of was not apparent. The plaintiff herself was the only person who gave any direct evidence as to her condition. Her physician did not make any physical examination, but simply took her word for her condition. Without a physical examination the defendant had no means of controverting any statement which the plaintiff might make. The character of her injury did not appear, and it was not a case from which the jury could otherwise determine the extent of her injury. In the court's opinion, this was a case in which the ends of justice would be better subserved, and the truth more likely discovered, by ordering a physical examination.

10 Removal of Foreign Bodies from Lung. E. C. Sewall, San Francisco
11 Occipito-Atlantoid and Atlanto-Axoid Dislocation. L. L. Thompson, Gridley.

1. **Migraine.**—Moffitt deplores the tendency to urge operation for the treatment of neurasthenia. He believes that more may often be accomplished for the man or woman with migraine by a rational mode of living, working and thinking than by drugs, eye-glasses or operation.

5. **Determination of Sex.**—This question the author claims to have studied in her own case, in other women and in animals. Her reasonings in the matter have led her to believe that the greater the differentiation the higher the species, the more limited the reproductive power the more confined the method of reproduction. All extraneous influence affecting reproduction in the lower orders has passed away in the higher, and the power to produce the female is vested, so to speak, not in the individual, but in the ovum. That is to say, no condition affecting the nurture of the mother herself has any power in determining the sex of the offspring, but it

is determined by some condition inherent in the ovum, and common to all women at certain times. The male element has no influence in determining the sex. The sex of the future child is determined at impregnation by the condition of the ovum at the time. The fullest development of the ovum produces the female after impregnation. The male is produced by impregnation either before the fullest development of the ovum, or after waste begins to take place. Given normal physical conditions of health in the woman, that is to say, menstrual period recurring every twenty-eight days and continuing five days, the ovum reaches its fullest development immediately before menstruation and continues to preserve that condition until two days after the cessation of the period. If fertilization takes place from one to two days before the period or from one to two days after the cessation of the period a female results, the latter method being the most successful. If fertilization takes place from four to eight days after the cessation of the period or from three to five days before menstruation the male results, the latter being unusual.

McConnel asserts that every experiment carefully carried out has resulted as desired, when the conditions of health and of physical development have been normal. She says further that if fertilization takes place from five to three days before the period a male results, and in that case menstruation demonstrates itself and the child appears to be born before its time; but if fertilization takes place just before the period, say from two to one days, a female results, and menstruation does not generally demonstrate itself, and the birth takes place three weeks later than it was expected. The count should be taken from the date of conception, whereas women count it from the cessation of the period; hence if a male is conceived days before the period, which for some unknown reason demonstrates itself in this case, he is born at a corresponding time, but the mother has counted from the cessation of the period and is out some eight days or so; whereas, if conception takes place immediately before the period a female results, but for some reason menstruation does not in that case appear and the mother counts from the cessation of the previous period and thinks she has had to wait some three weeks over her time. McConnel cannot account for these phenomena unless one may reason that if conception takes place immediately before the period that the ovum being then in its most perfect condition nature is satisfied, and the internal mouth of the uterus is closed; whereas if conception takes place some days before the fullest development of the ovum, the ordinary processes continue because the most perfect state of the ovum has not been accomplished although conception has taken place.

8. **Treatment of Tic in Childhood.**—The details of the treatment employed by Fleischner are as follows: (1) A very complete physical examination is made to be certain that the patient is not suffering from some irritation, such as follicular conjunctivitis, errors of refraction, polyps in the nose, adenoids, tight clothing, which may have been responsible, not for the tic, but for the original voluntary motion that preceded the tic and of which the tic movement is a repetition. (2) The patient is immediately taken out of school, if possible is sent to the country. (3) He is put on an easily assimilated diet, forcing the milk and eggs. (4) He is made to rest one-half hour before his meals and one-half hour after his meals. (5) The children are given very light evening meals and are put to bed within two hours of that time depending on their age. (6) Small doses of sodium or strontium bromid are given for two weeks. (7) Educational treatment. Under this heading are included those methods which enable the patient by training to control his involuntary partially or wholly subconscious movements. The method employed in the cases treated depends on the fact that the tic movements can be stopped by an effort of the will for a longer or shorter period of time by all patients. In other words, it depends on concentration. The effect of the treatment is obvious, the patient controls his tic by force of will.

19. **Treatment of Stuttering.**—The treatment resorted to in these cases in Holland is described by Van Baggen. The first thing to do when treating a stutterer, he says, is to give him a rest. So the stutterer is forbidden to speak. Some do not stutter when they speak in a whisper. These are allowed to whisper, but not more than is strictly necessary. At the same time exercises are given for breathing, vocal and articulating muscles. These exercises not only aim at the development of the muscles but also tend to favorably influence the nerve fibers associated to the muscle. Therefore the exercises must be carefully chosen in such a manner as to produce a quiet, regular movement of the muscles by means of which all stuttering is excluded. After some days the patient is allowed to speak, in the beginning only in the presence of the teacher and only for a few moments. At a later period when the patient does not stutter the discourses are prolonged. These early conversations, during which stuttering must be carefully avoided, are for the specialist one of the most difficult parts of the cure. They require the exercise of the greatest tact in leading the conversation in such a manner as to prevent the patient from stuttering. When the latter has spoken fluently for some days with his teacher without any stuttering he is allowed to converse a few moments with his family and friends. When we have succeeded so far we generally notice a rapid progress. The patient regains his self-confidence and the constant apprehension associated with his speech disappears; this has a favorable influence on the entire nervous system. When the cure is completed the patient must remain under the control of the specialist for some time, while also continuing the exercises with increasingly longer intervals. If there are adherent symptoms the exercises for the breathing, vocal and articulating muscles must be combined with slow, regular movements of the limbs. Those voluntary movements suppress the involuntary convulsions.

Van Baggen says, that when treating a stutterer it is necessary to take into consideration not only the manifest symptoms of the disease but also the temperament of the patient. The timid patient who suffers deeply from the humiliation entailed by his infirmity must be dealt with in a manner different from that with which one deals with the heedless stutterer who feels only the irksomeness of his impediment. The spoiled, undisciplined child requires firmer management, while the bashful little stutterer must be approached with kindness. The success of the treatment depends much on a good understanding between the patient and the specialist.

24. **Tympano-Mastoiditis Exhibiting Mental Symptoms.**—Amberg cites a case of mastoiditis in a hysterical subject, which was accompanied by such prominent mental symptoms as to cause grave suspicions of brain abscess. The patient recovered perfectly after a prolonged stay in the hospital.

25. **Extensive Herpes.**—The patient was a lady, aged 68. On March 8 the herpes appeared, simultaneously on the left upper lip, in the left naris, left inner canthus, in the left middle ear and external auditory canal from the meatus back. An enormous serosanious discharge accompanied the aural lesion, saturating cloth after cloth. The membrana tympani and the ossicles were carried away. Hearing was nil with the watch at contact. Illumination showed the pulsating arch of the auditory artery. Treatment consisted in a free application of a saturated solution of alum to the naris, the lip and the inner canthus, and instillation of the same freely into the auditory canal with boric acid. The external lesions were immediately subdued; the aural discharge became purulent. After a week the alum solution was dropped, and irrigation of the canal and subsequent boric acid packing continued. The purulent discharge gradually diminished.

On the twentieth day a narrow rim of new tissue was noticed at the seat of the destroyed membrane. The packing was dropped, and twice daily gentle irrigation was made with weak boric acid solution. The rim of new tissue increased and the lumen gradually diminished. The arterial pulsations remained visible until the complete closure of the opening. This occurred on the forty-second day.

26. **Action of Colloidal Platinum.**—Temporary leukolysis followed by polynuclear leukocytosis is reported as caused by injection of colloidal metals into normal blood or that showing polymorphonuclear leukocytosis. If polymorphonuclear leukocytosis could be induced in this manner in myelogenous leukemia by such injections, one might cause replacement of myelocytes by polymorphonuclear leukocytes, which change is said to accompany the improvement in this disease under roentgenotherapy. Dayton has administered isotonic, stabilized, electrically prepared colloidal platinum, in doses of 5 c.c. hypodermically, daily or every two days, to two patients with myelogenous leukemia. No constant effects on temperature, pulse, respiration or subjective symptoms were noted, and the disease apparently progressed as usual. The only correspondence in the blood changes with those reported as occurring in normal blood or that with polymorphonuclear leukocytosis was a temporary fall in the percentage of polymorphonuclear leukocytes, but this was not accompanied in both cases by a fall in the total leukocyte count. The neutrophil myelocytes coincidently rose and the mast cells fell. Aside from these changes, the variations in the blood were no greater than are common in this disease.

39 Transperitoneal and Suprapubic Approach to Tumors of Bladder. C. L. Scudder, Boston.

33. **Primary Neoplasms of Spermatic Cord.**—The tumor in Stetten's case apparently develops from the areolar tissue of the cord. Microscopically it was a very cellular, mixed small and large spindle-cell sarcoma, as is also a nodule removed from the perineum. A nodule higher up in the cord also gave the same histologic findings. This latter nodule was apparently a metastasis in one of the spermatic veins. Many of the cells of the tumor showed active mitosis and the intercellular connective tissue was rather scant. The tumor was moderately vascular. A month later a small nodule was noted in the wall of the right lower abdomen, seemingly a thrombus in the right superficial epigastric vein. This was excised under local anesthesia and found to be a sarcomatous plug in the vein, of the same nature as the primary tumor. Three months after this second operation there was found a large mass involving the perineum and extending into the root of the penis, seemingly infiltrating along the vascular channels of the corpora cavernosa and corpus spongiosum and producing a psuedo priapism without greatly increasing the diameter of the organ. There was a large mass over the left saphenous opening, most probably a metastasis via the superficial external pudic vein. Two smaller nodules were found along the course of the left superficial epigastric vein and one in the left superficial circumflex iliac. The patient had a slight cough but no signs of fluid or consolidation in the chest. There were occasional moist râles. Abdominal examination was negative.

Stetten subjected the man to a course of treatment with Coley's fluid, which he stood well. He began with ¼ drop and increased the dose gradually to 5 drops every day, injecting the fluid directly into the tumors. There was a moderate general reaction and the nodules that were injected did really decrease in size. Soon, however, a new nodule appeared on the left chest wall; metastases were noted along the vessels of both arms; fluid appeared in both chests; an increasing edema of the penis, scrotum and lower extremities, due to actual compression, developed; cachexia became very pronounced and progressive, and the patient died 6 months after the first operation. No autopsy was obtained.

46 *Surgical Treatment of Pellagra; Report of Sixteen Cases. T. J. Bennett and Z. T. Scott, Austin, Texas.
47 New Methods of Syphilis Diagnosis and Therapy. I. C. Chase, Fort Worth.

45. **Public Health and Vital Statistics.**—O'Farrell sums up his remarks as follows: When we are proud to register our live stock; when we teach young men how to care for the health and well being of our hogs, horses and cattle; when we extend to such stock the solicitous attention of a well-supported department of our national government; when we carefully conserve any national resources, spending as we do millions of the common fund for reclaiming vast areas of land for our people to occupy, we are wise. But, when we are careless about registering our babies; when we fail to teach our doctors how to protect the human health; when we do not properly safeguard our human food-supply; when we neglect the conservation of the most important of all our resources, because, forsooth, it does not appear merchantable, we are, most assuredly, otherwise.

46. **Surgical Treatment of Pellagra.**—The surgical treatment of pellagra by the transfusion of blood from a healthy donor to the patient originated by Cole and Winthrop of Mobile, was used in each of the sixteen cases reported by Bennett and Scott. The results have been gratifying, a cure in thirteen cases (73 per cent.), meaning no return of the symptoms to date. Of ten patients who either refused transfusion or were treated with medicine prior to the adoption of the transfusion method, seven are now dead, and three are awaiting transfusion at the present time.

54. **Paralytic Dislocations and Subluxations of Hip-Joint.**—The clinical history and dynamics of this condition are discussed by Sever. His interest was stimulated by twenty-six personal cases, twenty-two of which were iliac subluxations. Sever attempted to dislocate a hip in rabbits and cats, but, owing to the firm support of the ligaments and muscles, besides the unusually deep acetabulum, the short neck of the femur, which is at very nearly a right angle to the long axis of the shaft, and the high great trochanter, he found it impossible, even when using great force. He then decided to divide certain nerves singly and together in separate animals so as to produce a condition of paralysis of the hip and leg muscles, somewhat analogous to that seen in anterior poliomyelitis. This condition he could not reproduce exactly, for in cutting the nerve trunks he not only destroyed the motor impulses, but also the sensory. The five cats all lived about three months, long enough to show changes in the joint were any going to occur. On careful dissection and inspection no changes were visible, nor could the hip be dislocated. All of the cats but one had the anterior crural divided, in the other the great sciatic was divided.

Sever concludes that subluxations of the hip-joint are not uncommon conditions following paralysis of the thigh and peritrochanteric muscles. The most important factors in their production are the unopposed contractions of the non-paralyzed muscles. The two muscles which escape the paralysis most frequently are the adductors and the tensor vagina femoris. The most common type of subluxation is upward and backward on to the ilium. The changes from atrophy in the femur and acetabulum are practically constant, and consist of a coxa valga and a shallow, flattened and elongated acetabulum. The treatment should be directed toward correcting the contractions and reducing the dislocation of the hip. The muscles may be elongated by stretching, by means of plaster casts, bed traction or division. The best method in Sever's opinion of keeping the hip reduced is by means of an arthrodesis, although this is not practical in all cases. Without treatment the tendency is toward progressive deformity. With treatment the conditions may be permanently helped. Complicating conditions make a total cure impossible, but a more useful leg should be assured under proper treatment. Walking after arthrodesis is often improved. In some cases splints may be altogether discarded. Sever does not regard it advisable to do an arthrodesis on both hips, or on any joint other than the hip and ankle on the same leg.

66. **Arthroplasty for Ankylosis.**—The following points summarize Wiener's paper: Brisement force is useful in cases only of synovial adhesions; in true bony or fibrous union it is apt to do harm. The interposition of absorbable or non-absorbable foreign bodies does not give good results. The interposition of living tissues such as hernial or hydrocele sac is unsatisfactory, as bony ankylosis regularly results. Arthroplasty is a very valuable procedure in cases of bony or fibrous ankylosis of the jaw, shoulder, elbow, hip and knee. Either muscle, or fascia with fatty tissue, should constitute the interposed flap.

67. **Curved Incision in Surgical Work.**—The advantages Bowles claims for the curved incision, as compared with the straight, are the following: There is a better exposure of the subcutaneous field, giving much more room to work. Less retraction is required, and this means less assistance needed, fewer fingers in the wound, and consequently less danger of infection. In looking for a foreign body imbedded in the tissues, it is found more readily and with less traumatism. In removing a growth, a much better exposure of the sides and base is possible, rendering the work of dissecting and shelling it out far less difficult. In case the work calls for an incision into the muscular tissues, they are more accessible, and the intermuscular septa and lines of cleavage are more readily found than where the straight incision has been employed and retractors have to be used to haul the sides of the wound in one direction or the other. And lastly the incision is just as readily closed, and heals as well and as quickly. The points to be observed are to direct the base of [illegible] toward the source of the blood supply, especially in [illegible] which the depth of the flap is great in proportio[illegible] length of the incision. And if infection is feared, as [illegible] in which there is much dead space below the flap that [illegible] be perfectly obliterated, a small gauze or gutta-percha drain should be slipped in between two of the stitches or brought out through a puncture in the center of the flap.

81. **Action of Vagus Nerve on Human Heart.**—The authors' records show that stimulation of the vagus nerve by pressure in a man with an anatomically normal heart has produced a marked slowing of both auricles and ventricles, a depression of conductivity of the heart beat from auricles to ventricles, and probably has resulted in a diminution in the force of contraction of the left ventricle. Stimulation of the right vagus nerve apparently has caused stimulation of the left. The left vagus stimulation seemed to have a more marked effect on the conduction of the cardiac stimulus from auricles to ventricles. While no significant changes were noted in this case in the action current due to auricular contraction, right-sided vagus stimulation seemed to increase the action current of the ventricles, giving rise to an increased R wave, while left vagus stimulation apparently produces the opposite effect. There is no evidence in the curves that any changes in excitability of the auricles or ventricles are produced by vagus stimulation. The records supply definite evidence to the effect that the vagus nerve controls the heart in a way which is very similar in man and in other mammals. In hearts showing auricular fibrillation mechanical stimulation of the right vagus nerve causes, as a rule, marked slowing or stoppage of ventricular rhythm, without producing any appreciable effect in the electrocardiographic record of the auricular fibrillation. The ventricular pauses are apparently due to the blocking of stimuli from the auricles. The force of ventricular systole is distinctly weakened for several beats after vagus stimulation, and ectopic ventricular systoles have been seen in several instances, apparently the result of the vagus action. There may, in some cases, be lowered excitability of the ventricles, while no constant change is seen in the size of the electric complexes representing ventricular systole.

82. **Complement Deviation in Scarlet Fever.**—Sera from 250 cases of scarlet fever, representing all stages of the disease, were examined by Kolmer according to the following plan:

1. According to the Wassermann system with the following antigens: (a) With alcoholic extract of luetic liver used as antigen, there were five, or 2 per cent., positive reactions out of the 250 sera tested. In these five cases positive reactions also resulted with scarlet fever liver antigen and with active and inactivated serum of the Noguchi system. (b) With an alcoholic extract of scarlet fever liver used as antigen; the 250 sera were tested with this antigen. The antigen itself was tested with a number of normal and syphilitic sera and was found to be antigenic in dosage from 0.25 to 0.3 c.c., and free of anticomplementary and hemolytic action. The results were practically identical with those resulting from the use of the luetic liver antigen. Deviation of complement resulted in six cases, or 2.4 per cent. These included the five cases given above with the addition of a case which also gave positive reactions with active and inactivated serum, according to the Noguchi system.

2. According to the Noguchi system: (a) With active serum there were sixteen, or 6.4 per cent., positive reactions. Five of these were with the five cases yielding positive Wassermann results. In five, or 2 per cent., of the cases the reaction was positive with active serum alone, and negative with inactivated serum by both the Noguchi and Wassermann systems. In six cases the reactions were positive with both the active and inactivated serum. In other words, with the Noguchi system there occurred eleven more positive reactions than with the Wassermann system, five of these being with active serum alone. (b) The first ninety of these reactions were made with alcoholic extract of luetic liver used as antigen, and it is well to note that four of the positive reactions which were obtained with active serum were made with this antigen.

The remaining 140 cases were tested with an antigen of acetone insoluble lipoids from which but one positive reaction with active serum resulted. Complete hemolysis occurred in 229 cases, or 88.1 per cent., and partial hemolysis in twenty-one cases, or 11.9 per cent. The amount of complement, 0.1 c.c. of guinea-pig serum, was employed because this is the usual dose recommended, although serum from different animals varies in its complement content. It emphasizes the necessity of careful titration of complement, for an excess of this factor, up to a certain limit, will give hemolysis with a decreased amount of hemolysin. The presence of anti-sheep hemolysin in normal human serum probably accounts for the negative Wassermann reaction with serum containing small amounts of syphilitic antibody. On the other hand, normal active serum will give a positive Noguchi reaction. For these reasons Kolmer agrees with Kaplan that a Wassermann and Noguchi reaction should be performed with each serum, the one acting as a control on the other.

83. **Cultivation of Tissues in Vitro.**—It is emphasized by Carrel and Burrows that in the preparation of a culture in fluid medium, an important requisite is a suitable support for the growing cells. Although fibrin is an efficient support, it can be replaced by other bodies, such as cover-glass, cotton, silk, etc. The cells grow in the fluid only if they meet with this condition of support. Therefore, the fragments of tissue must be very small in order to remain adherent to the cover glass, and the fluid must be spread out in a very thin layer about them. The growing cells cling to and spread over the surface of the glass. But if cotton threads are placed in the fluid, the cells have a better support and grow luxuriantly around them. The plasmatic medium is, beyond comparison, the optimum medium thus far studied for the growth of tissues. But cells can also grow in other media and under many different conditions.

84. **Effect of Salvarsan on Heart in Dogs.**—It was found by Auer that the intravenous infusion of 0.5 per cent. acid salvarsan causes a weakening of the heart which is usually fatal. The intravenous infusion of 0.5 per cent. alkaline salvarsan causes no marked apparent effect on the heart, but its factors of safety may be so reduced in some instances that a slight extra strain produces fibrillation and death. The animals stood the infusion of salvarsan in 0.2 per cent. or 0.5 per cent. alkaline solution very well, even with the enormous doses infused (20 to 40 mg. per kilo of body weight). No marked changes of either heart volume, blood-pressure or heart-rate are recorded. In one instance the blood-pressure and heart-rate were practically unaltered after the infusion; the heart, however, showed a moderate dilatation which persisted for about twenty minutes after the infusion. Thirty-five minutes after the infusion, the heart was apparently normal. But on removing the heart from the oncometer, and handling it very gently, it passed at once into fibrillation, from which it did not recover. Similar effects were observed in other experiments where the alkaline solution was infused. On the other hand, some hearts of the same series of experiments stood manipulation very well, and only a very transitory change in the heart's action was observed. The infusion of 0.5 per cent. acid salvarsan produces swiftly a moderate dilatation of the heart; then the blood-pressure begins to fall and reaches a low level rather promptly. During this fall, the pulse pressure diminishes rapidly, and at the lowest level of blood-pressure the heart-rate is very slow. After a low blood-pressure has been reached, the heart dilates still more and may even stop in diastole for a period of seconds. Then the heart begins to beat again, but the beats are weak and hardly affect the lever of the membrane manometer which is connected with the carotid artery. From this state the animal does not recover, though the heart, as a rule, keeps on beating feebly for a number of minutes. Results similar to those described above were obtained in practically all of the ten experiments which were made with the 0.5 per cent. acid solution.

85. **Chemo-Immunologic Studies on Localized Injections.**—Lamar found that in the test tube, sodium linoleate and sodium linolenate kill and dissolve virulent pneumococci more rapidly and in higher dilutions than sodium oleate; otherwise

their action is the same. The intensity of action on the cocci is directly proportional to the degree of unsaturation of the acid. Blood serum inhibits the bacteriolytic and hemolytic action of unsaturated soaps partially or completely, according to definite quantitative relations between serum and soap. Small quantities of serum completely inhibit the action of dilute soap solutions, but even whole serum does not prevent bacteriolysis and hemolysis by relatively concentrated soap solutions, i. e., 1 per cent. and 0.5 per cent. A given quantity of serum inhibits the action of the soaps in inverse ratio to their degree of unsaturation. The hemolytic and bacteriolytic action of soaps of the unsaturated fatty acids is probably due in part to their avidity for protein and not wholly to their ability to dissolve lipoids. Attempts to prevent serum inhibition of the lytic action of sodium linoleate and sodium linolenate were unsuccessful. The more unsaturated soaps are not as efficient in preventing fatal pneumococci infection of animals as sodium oleate.

86. **Rate of Regeneration of Blood Platelets.**—By repeatedly withdrawing, defibrinating and reinjecting blood, it was evident to Duke that the platelet count in dogs can be reduced to an extremely low level. When the reduction in platelets and fibrinogen has been carried to an extreme degree the animals display a marked tendency to bleed. The regeneration of platelets after their removal by defibrination is remarkably rapid and amounts, on an average, to about one-fifth of the entire number in the blood per day. From the experiments and from observations on the platelet count in human beings, Duke believes that under the usual conditions of life platelets are utilized or destroyed and replaced in enormous numbers daily, and that the life-cycle of the platelet is extremely short, possibly a matter of a few days.

88. **Mechanism of Chlorin Retention in Pneumonia.**—The following conclusions are drawn by Medigreceanu from an analysis of the protocols of the experiments performed by him: 1. The chlorin output is very much diminished during the process of experimental pneumonia in dogs. The quantity of chlorin retained in the patients with well developed exudates is much larger than the exudate could account for. 2. Turpentine pleurisy in dogs also is associated with a retention of chlorin, but this is not so marked as in pneumonia. There is no direct quantitative relation between the water output and the chlorin excretion. 3. Rabbits with pneumococcal septicemia did not retain chlorin in any phase of the disease, a fact which Hutchinson has also noticed. The author deems it justifiable to conclude that the retention of chlorin in the organism in the course of pneumonia is conditioned by more than one factor. The formation of the exeduate is one of these factors, but it alone is not capable of producing the same degree of chlorin retention as occurs in pneumonia. The additional factors are not yet determined; but it may be stated that the retention of chlorin is probably not due to the general effect of the pneumococcus on the organism or to its injury to the kidney. The principal cause of the retention seems, therefore, to be due to local changes associated with the pulmonary condition.

90. **Experimental Nephritis.**—The physiologic study of experimental nephritis caused by poisons of bacterial origin demonstrated to Pearce and Eisenbrey that the poisons may produce types of nephritis in which either vascular or tubular changes predominate. Diphtheria toxin produces a nephritis which in its late stage is of the vascular type, but in its early stage is distinctly tubular. Tuberculin and mallein uniformly cause lesions of the tubular type, which do not pass into the vascular type. Nephrotoxic and hemolytic immune sera cause changes in the kidneys which by physiologic methods of observation present no evidence of vascular injury, but which are anatomically characterized by exudative glomerular lesions of moderate severity. This discrepancy between the results of anatomic and physiologic study indicates that a lesion of the membrane controlling the passage of fluids may occur without alteration in the power of the vessels to contract and dilate. This fact is shown clearly by the lesion caused by hemolytic immune serum, which is in sharp contrast to the lesion caused by diphtheria toxin, since the latter substance not only alters the *permeability* of the membranes but also influences markedly the power of the vessels to contract and dilate. It is necessary therefore if the term "vascular" is used in its broadest sense, to recognize three types of vascular nephritis: (1) one in which little or no anatomic evidence of vascular injury is found, but in which physiologic methods show profound vascular changes, as in arsenic nephritis; (2) one in which anatomic evidence of vascular (exudative) injury is prominent, but in which the physiologic tests are negative, as in nephritis caused by a hemolytic immune serum, and (3) one in which both anatomic and physiologic changes are prominent, as in diphtheria toxin nephritis.

92. **Nerve Fibrillæ in Pulmonary Artery of Dog.**—By a method of *intra vitam* staining with methylene blue Karsner succeeded in demonstrating the presence of nerve filaments in the muscular coat of the pulmonary artery.

102. **Genito-Urinary Lesions.**—It has often been stated that when scrapings are made from the different urinary organs the epithelia appear very similar and cannot be differentiated. This is probably true, says Wyeth, but such scrapings are no criterion for the differentiation of epithelia which are bound to become altered to a considerable degree by the scraping. If the epithelia are carefully studied *in situ*, it will soon be found that the epithelia lining the different organs are decidedly different, and they can undoubtedly be distinguished in the urine, so that a definite and correct diagnosis can be made in the great majority of cases.

103. **Cerebral Rheumatism.**—The interesting pathologic features of the cases reported by Williams in addition to the meningeal and cellular changes already described by other observers, are the presence of numerous cells similar in every respect to the so-called plasma cells, numbers of fatty granular cells, and also an abundance of globular, pale blue staining bodies, probably of albuminous nature, having their origin from the disintegrated tissue. The great intensity as well as the diffuseness of the cellular changes, Williams says, are exceptional, as is also the vast extent and degree of the neuronophagocytosis. He reviews the clinical history of this affection.

104. **Triple Rhythm Heart Block.**—In an individual studied by Benedict the arterial pulse was fairly strong and regular, twenty-five a minute. The jugular pulse was three times as frequent and in perfect triple time, but careful inspection of the neck showed that the auricular beat immediately preceding the ventricular, was imaginary, or, at most, so faint as to be imperceptible, although the perfection and steadiness of the rhythm at first gave the impression that we had to deal with a three to one ratio of auricular to ventricular contractions. Expressed in musical notation, the condition was as follows: The treble representing the auricular, the bass the ventricular beat. It is not, however, implied that the tone of either was exactly located. Benedict suggests that as heart block is a rare condition, with which no single physician can as yet have a large experience, it is perfectly possible that the rhythm may not be so constant for the individual case as has been implied in some articles, and that a failure of the auricle to beat at the proper instant may not be at all uncommon. It is also worth while to observe the jugular wave in normal cases and in cases of valvular lesion without suspicion of heart block. There is by no means always a single pulsation in the neck to each heart beat, but often two or three slight waves. Hence, in any case of bradycardia, one who has read much about heart block and has had little or no experience with it, but who has an ambition to detect a case, may deceive himself as to the occurrence of a succession of auricular impulses.

In Benedict's case there were two marked jugular waves with a rest at the instant when the third wave would be expected, and the condition seemed to correspond as closely as could be with the type, with the exception noted. But, without kymographic experiments, Benedict says that with a very slowly acting ventricle and a firm closure of the auriculoventricular valve, it is conceivable that a double wave might occur in the blood in the auricle and great veins, without any secondary contraction of the auricle. Theoretically, the auricular contraction in the musical notation should be indicated as preceding the ventricular. Practically, it seemed to occur at exactly the same time as the radial pulse.

111. **Crotalin Treatment of Epilepsy.**—The solution which Spangler finds most satisfactory and effective consists of the dried, crystal-like scales, from the venom of *Crotalus horridus*, dissolved in sterile water, to which has been added a few drops of trikresol for its preservation and antiseptic effect. This sterile, antiseptic solution is put into sterilized ampoules, holding 1 c.c. each and sealed. Each ampoule contains one dose, which is made as strong as desired, i. e., each c.c. of solution represents 1/22, 1/75, 1/100 of a grain of the venom.

Included in the thirty-six cases cited by Spangler are twenty-four patients who were subject to only major attacks, grand mal; eleven who were subject to both major and minor attacks, and one in whom only the petit mal form was present. In nine out of the thirty-six cases the convulsions occurred in series.

A family history of epilepsy was present in nine of these cases; alcoholism in four; insanity in three; and in the remaining twenty cases of the series the family history was negative, so far as hereditary influences are usually considered. Four cases were preceded by convulsions in infancy, two by chorea, three by scarlet fever, and in one case epileptic attacks developed while the eruption of measles was present. Two cases followed attacks of typhoid and one case followed a heat prostration. There was a history of a fall (traumatism) in four of the cases, and of a severe fright in three. Menstrual irregularity was associated with the convulsions in four patients out of the series. In the remaining thirteen cases nothing of interest or importance could be elicited in regard to the previous history of the patient. The form of epilepsy most influenced by the venom is the so-called idiopathic or genuine epilepsy, for which there is no ascertainable cause. The patient may be subject to either the major, grand mal attacks, or the minor, petit mal, form may be the only evidence of the disease. In a number of Spangler's cases the grand mal type was replaced by the petit mal seizures before the intervals between the attacks were much lengthened.

The organic epilepsies, including those forms arising from traumatic lesions of the skull or brain, or those forms associated with focal organic disease of the brain, such as tumors, cannot be expected to yield to the venom treatment. Likewise, no influence on alcoholic epilepsy or epilepsy arising from uremic or eclamptic conditions can be looked for. While only three cures are reported by Spangler the general improvement in the patient's mental and physical condition was such as to lead him to urge the use of this remedy in these cases.

2. **Tuberculin Dispensaries.**—Evidence that proves the hollowness of these pretensions that stay in sanatoriums, combined with graduated exercises, can help the poor suffering from consumption is given by Wilkinson. He says that both rest and graduated exercise have long been employed in Germany in the treatment of consumption at sanatoriums, and the results of sanatorium treatment among the poor in Germany lend no encouragement to the view that sanatoriums can help the poor. Moeller, of the famous Belzig sanatorium, near Berlin, claimed that sanatorium methods by themselves cure only 10.9 per cent. of the patients. Arranged according to stages the results were: Stage 1, sanatorium methods alone cured 31.8 per cent. Stage 2, sanatorium methods alone cured 1.9 per cent. According to Moeller's later experiences, sanatorium methods alone may effect a cure in 25.3 per cent. of the cases of pulmonary tuberculosis of Stage 1 (German Board of Health classification), while tuberculin has secured the same results in his hands in 84.6 per cent. Weicker, the devoted pioneer of the Volks-sanatoriums of Germany, found that of every 100 patients treated in sanatoriums by rational methods alone, including exercises, at the end of one to one

and one-half years, forty-one; at the end of two to two and one-half years, fifty-one; at the end of three to three and one-half years, sixty-five, and at the end of four years eighty had lost their fitness for work or were dead. The death-rate was as follows: In one to one and one-half years, 25 per cent.; in two to two and one-half years, 38.4 per cent.; in three to three and one-half years, 55 per cent.; in four years, 56.7 per cent. Wilkinson emphasizes further that the aspect of sanatorium treatment is not encouraging when we read that 7.6 per cent. of patients in Stage 1 are unfit to work or are dead in one to one and one-half years, 19 per cent. in two to two and one-half years, 33.3 per cent. in three to three and one-half years, and 55.6 per cent. in four years.

Wilkinson insists on tuberculin serodiagnosis and serotherapy in tuberculosis. He endorses the dictum of Koch that in Stage 1 tuberculin cures pulmonary tuberculosis with certainty and that the routine use of tuberculin in the second stage of pulmonary tuberculosis is the best means of preventing mixed infections in all forms of open pulmonary tuberculosis. He knows no contraindication to the use of tuberculin except despair. Within the last year he has treated at his tuberculin dispensary more than 100 patients with pulmonary tuberculosis in all stages, and apart from the cases of mixed infections, always in an advanced stage of the disease, he has been unable to find any limitation circumscribing the use and value of tuberculin. Wilkinson admits, however, that it is not wise, except with certain precautions, to use tuberculin in cases of well marked renal disease. Renal disease is in itself, sooner or later, fatal, and there is not much object in curing a tuberculous lesion when there already exists a disease which in itself is likely to be fatal. By a proper course of tuberculin treatment, it is almost the rule that cough and expectoration cease, so that the victims themselves cease to be a danger to their friends and relations.

3. **Bacteriology of Toothbrushes.**—It is claimed by Smale and Jones that a toothbrush becomes septic after once using, each hair becoming an inoculation needle, and the person using it may be vaccinated with such germs as flourish on it. The toothbrush, therefore, as popularly used, namely, for many months, may be the origin of pyorrhea alveolaris, which may lead to such grave consequences as anemia, gastritis or arthritis. The prevalent tooth powders and tooth pastes as usually used do not render the toothbrush aseptic, and even 1 in 20 carbolic acid is not effectual in so doing. The authors insist that all toothbrushes should be boiled for five minutes before and after use. A new toothbrush can be used each day. Those wishing for a more prolonged use of a toothbrush can rinse the brush in trikresol (1 per cent.) or allow it to stand between use in formalin (10 per cent.). Their remarks are based on extended experiments.

4. **Frenkel System of Exercises for Tabes.**—A case is reported by Garson as illustrating the beneficial effects which result from the systematic practice of the exercises designed by Frenkel of Heiden for restoring the power of coordinate movements in persons affected by tabes dorsalis. It shows how a person who has been reduced to a state of almost complete invalidism may by this means regain the power of locomotion so as to be able to live a comfortable and useful life.

14 *Clinical Varieties of Undulant (Malta) Fever Met with in South Africa. A. Garrow.

15 *Pemphigus Contagiosus. R. H. Castor.

14. **Malta Fever in South Africa.**—This paper is founded on an experience with Malta fever extending over three years, during which time Garrow has been in practically daily contact with the disease or its sequelæ. He thinks that every case that one is likely to meet will find a place in one or other of the following groups: (1) *Acute type*—(a) malignant cases; (b) one-wave cases; (c) more than one-wave, or the undulant cases. (2) *Subacute type.* (3) *Chronic type.* (4) *Complicated,* including those cases which first come under observation on account of a complication or sequela of Malta fever, or during a concurrent illness. The clinical manifestations in a case of the chronic type are so entirely different from those found in one of the acute varieties that, but for the Widal test, Garrow says, it would be impossible to believe that both patients were suffering from the same disease. There is a connection, however, running throughout all the varieties, and the best conception of that is gained by remembering that the undulant type is what might be termed the central type. All the other types are but variations of it, depending on varying combinations of such factors as the quantity of the virus and the virulence of it, and the state of the defense forces of the patient. The undulatory type is characterized by intermittent waves or undulations of more or less remittent pyrexia of variable length and number, separated from one another by periods of variable length of temporary abatement or absence of symptoms. The acute one-wave type designates those cases characterized by simply one wave or undulation of varying length and severity, followed usually by a convalescence and recovery. The malignant type includes those acute cases characterized by great severity of symptoms and profound toxemia, and generally resulting in death. On the other side of the central type are the subacute and the chronic, in which, owing, perhaps, to a weakened virus, or a smaller quantity of it, or to more sluggish action of the defense forces of the body, the pyrexia is more or less subdued. The cases which go to form the complicated type are in the majority of cases subacute or chronic. Examples of each type are cited. Of the complicated type the following cases are mentioned: Pulmonary-pleural; hepatic; renal; nervous; simulating hip-joint disease.

15. **Pemphigus Contagiosus.**—Castor points out that pemphigus contagiosus is fairly common in Burma, contrary to the belief hitherto held. He recently came across six cases in one family. In three of these patients the eruption first appeared on the chin; in one it appeared on the forearm, in another it appeared on the abdomen, and in the infant on the forehead. The usual places, like the crotch, axilla, etc., were not attacked. The course the eruptions followed was the usual one. The sizes of the vesicles varied from a pea to about those covering the area of an inch. They did not affect the general health of the children. In one case there were only two vesicles, in another there were four. One case showed ten vesicles, and in the others there were several. The most diffused cases were in the children aged 10 months and 3 years, respectively, and in these two cases they gave rise to much discomfort and irritation. The cases lasted from one to three weeks. The treatment was cleanliness, frequent use of mercury lotion, and antiseptic powder dusting.

17 *Influence on Nursling's Syphilis of Injection of Salvarsan in the Mother. (Le salvarsan injecté à une mère en période d'allaitement peut-il influencer la syphilis de son nourrisson?) E. Jeanselme.

18 When Does the Head Become Engaged in Vertex Presentation? (Nouveaux documents sur l'époque de l'engagement dans les présentations du sommet.) Audebert and Baux.

17. **Can Syphilis in the Infant be Influenced by Injecting the Nursing Mother with Salvarsan?**—Jeanselme reports seven cases in which salvarsan was administered to the nursing mother, and compares the outcome with seven other cases that have been reported by others. In only six cases were beneficial results evident, and in these cases the infants were not kept under observation long enough for a decisive judgment as to the value of the method. The salvarsan injected into the nursing mother sometimes induces evident retrogression of the superficial lesions of the nursling, but they generally soon recur and sometimes in a more pronounced form. The deep or visceral syphilitic lesions are not benefited and may even become fatally aggravated under the influence of the injection in the mother. Before applying this indirect method of treating the infant, the condition of the principal viscera should be investigated and it should not be applied if they are found much impaired. Inunction with mercury proved suc-

cessful in arresting the serious symptoms of inherited syphilis which had resisted the indirect method of salvarsan treatment in his cases.

August, IV, No. 8, pp. 481-544

19 *Paralysis and Neuritis from Deficient Supply of Blood. (Paralysie et névrite d'origine ischémique.) R. Desplats and A. Baillet.
20 Digitalis. E. Robert-Tissot.
21 Case of Typhoid Bradycardia. Pierret and Darteville.

19. **Ischemic Paralysis and Neuritis.**—Desplats and Baillet present evidence to show that total or complete, durable or transient interference with the supply of blood to a peripheral nerve may entail serious functional disturbance and even degeneration of the nerve. When the ischemia is incomplete. as in Raynaud's disease, there may be paresis or paralysis without loss of electrical irritability. Complete ischemia is liable to entail neuritis, but if the circulation can be reestablished early the neuritis may rapidly retrogress before the nerve has become irremediably degenerated. If on the other hand the blood-supply is permanently shut off, degeneration of the nerve seems inevitable. Four cases of the various types are reported and compared with the few similar ones in the literature, especially with the fourteen cases of atrophy and paralysis following ligation of an artery, cited by Porta and Broca. The electric excitability of the nerve was not tested in these cases, but, taken in connection with the personal cases reported, they sustain the possibility of a paralysis. spreading out funnel-shaped, with degenerative neuritis, solely as the result of interference with the blood-supply. In the cases reported there had been no compression of the nerve sufficient to account for the disturbances. The theory of an ischemic origin for paralysis and neuritis in certain cases explains also those that follow severe chilling, as this interferes more or less with the circulation in the region.

Bulletin de l'Académie de Médecine, Paris

22 Spinal Anesthesia. (Rachianesthésie.) P. Reclus and E. Schwartz.

July 25, No. 30, pp. 78-108

23 *General Anesthesia with Part of Circulation Excluded. (De l'anesthésie générale avec circulation réduite ou exclusion des quatre membres dans l'anesthésie générale.) H. Delagénière.

23. **General Anesthesia with Part of Circulation Excluded.**—Delagénière has applied the method according to Klapp's technic in 1,144 cases, using chloroform, and in 35 with ether. An elastic band is applied to the upper part of each leg and arm, drawn tight enough to arrest both arterial and venous circulation. When the constriction is removed, the blood and tissues thus excluded from contact with the anesthetic, dilute and take it up rapidly. The patient rouses at once or in about ten minutes, and the postanesthetic disturbances are reduced in frequency and intensity. In case of accident, removing one or more of the bands flushes the system with fresh blood and starts up the respiration anew. The members feel a little numb or there may be minute ecchymoses, and postoperative phlebitis developed in four of his total 1,179 cases, but in three of these cases the operation had been for a gynecologic trouble and the edge of the inclined plane or the leg supports may have been responsible for this complication. Heart and vascular disease or general infections may contra-indicate the method in certain cases, but he asserts that it has special superior advantages in all cases of kidney and liver disease.

24 *Perforating Sigmoiditis. (D[illegible] [illegible] sigmoidiennes perforantes avec péritoni[illegible] [illegible] M. Patel.
25 *Experimental Grafts of Ar[illegible] [illegible] expérimentales sur les greffes vasculair[illegible] [illegible]rd, L. Tavernier and E. Perrin.
26 *Conservative Treatment of Osteosarcoma. G. Tisserand.

24. **Perforation from Inflammation at the Sigmoid Flexure.**—Patel discusses the diffuse peritonitis from simple inflammation at the flexure causing perforation. He has compiled twenty-eight cases, all but eight being in men over 35. The trouble is traceable to a diverticulum in most cases, he thinks. The details of fourteen cases are given in which an operation was attempted and of fourteen without, all confirmed by necropsy. An early operation and modern methods of managing the peritonitis may yet succeed in saving patients, although to date he knows of no case of recovery.

25. **Experimental Grafts of Arteries.**—The experiences related show the factors to be especially heeded in surgery of blood vessels. The work was done on twelve dogs.

26. **Conservative Treatment of Osteosarcoma.**—In the two cases reported by Tisserand the treatment gave perfect functional results. The patients were girls of 13 and 20 and the growth was in the fibula in one and in the ulna close to the wrist in the other. He ascribes the fine outcome to the fact that he was able to leave intact the lower end of the ulna articulating with the wrist. A flap of periosteum was left when the segment of fibula was removed and the bone regenerated from this.

30 *Relative Frequency of Symptomless Tuberculous Infection and Tuberculosis at Different Ages. A. Calmette, V. Grysez and R. Letulle.

27. **Salvarsan and the Internal Ear.**—Félix reviews forty-six articles that have appeared on syphilitic lesions of the auditory nerve with or without administration of salvarsan or any preparation of arsenic. Without deciding whether the salvarsan is or is not responsible for the disturbances in the labyrinth that have been observed after its use, he remarks that the data cited confirm the importance of careful examination of the ear before giving salvarsan and refraining from its use in case there is evidence to show that the organ of hearing and equilibration was impaired before the patient had contracted syphilis. The occupations which predispose to ear disturbances, such as boiler-making, and a history of an old internal ear disease, should positively exclude the patient from salvarsan treatment, and the greatest caution is necessary in employing salvarsan if the patient has been taking arsenic for some time in any form. He reports a personal case in which a young man became suddenly deaf, with tinnitus and vertigo, two weeks after an injection of salvarsan, the sixth week after contracting syphilis. It was learned that the young man for several years had been slightly deaf in one ear. In another case, years before salvarsan had been heard of, a patient developed deafness and tinnitus three weeks after infection with syphilis; Delsaux has reported a similar case one month after the primary sore; Rozier has reported a case in which the primary sore and the labyrinthitis developed almost simultaneously; Stümpke two with an interval of four and five months; Politzer reported in 1901 a case in which the interval was only a week, and Habermann in 1896 reported sixty-six cases of syphilitic labyrinthitis with intervals of only three to nine weeks between the primary sore and the internal ear trouble in sixteen. All of these cases preceded the discovery of salvarsan.

28. **Sudden Death from Scarlatinal Myocarditis.**—Weill and Mouriquand assert that myocarditis is the cause of sudden death in convalescents from scarlet fever much more frequently than is generally recognized, and cite a case in which a girl of 15, apparently recovered from a mild attack of scarlet fever, died suddenly while at stool. In another case an infant of 18 months had been in the diphtheria ward for a month on suspicion of diphtheria but with negative bacteriologic findings. Then a scarlatinal eruption developed and faded and the child was apparently doing well when it suddenly died. Necropsy revealed acute myocarditis, notwithstanding the total absence of myocarditic symptoms during life.

30. **Relative Frequency of Symptomless Tuberculous Infection and Tuberculosis at Different Ages.**—The tuberculin skin test was applied to 1,226 children at Lille and the children

were examined the fifth or sixth day thereafter, a control scarification without tuberculin having been made on each. A positive reaction was observed in 8.7 per cent. of the 273 children less than a year old; in 22.1 per cent. of the 145 between 1 and 2; in 53.8 per cent. of the 206 between 2 and 5; in 81.4 per cent. of the 366 between 5 and 15, and in 87.7 per cent. of the 236 over 15. And yet, notwithstanding the large number of children shown by the tuberculin test to be infected, only an average of 24 per cent. develop tuberculosis later; that is, this is the death-rate from tuberculosis in the town. All the others, fully 66 per cent., escape tuberculosis, the infection remaining permanently latent or occult, while the subjects are apparently healthy and succumb in time to entirely different diseases. Calmette concludes by emphasizing the necessity for distinguishing between the occult infection revealed merely by the tuberculin tests, and tuberculosis, "the disease characterized from the beginning by the follicular lesions resulting from the symbiotic existence of the tubercle bacillus with the cells of the different organs."

August 16, No. 33, pp. 385-396

33 Perithelioma an Illogical and Artificial Term. (Le périthéliome.) G. Roussy and P. Ameuille.

31. **Arcus Senilis.**—Marie and Laroche present evidence to prove that the greyish crescent is in reality a deposit of cholesterin. Research on the lipoids and cholesterin in different tissues and in the blood seems to promise to throw light on certain hitherto obscure points and suggest unsuspected connections between them, such as in the effect of epinephrin injected into animals which entails both atheroma and hypercholesterinemia.

32. **Medical Geography of the Plague.**—Guiart shows by historical review and five maps how pneumonic plague seems to be restricted to the region between the isothermal lines of 5 and 10 C. (41 and 50 F.), apparently being favored by cold; the epidemics to date have broken out in the winter. Europe, lower Canada, the upper Missouri and British Columbia are in the region involved. Bubonic plague on the other hand clings to the region between the isothermal lines of 20 and 25 C. (68 and 77 F.) and a certain amount of heat is necessary for its spread.

Archiv für Verdauungs-Krankheiten, Berlin

August, XVII, No. 4, pp. 395-510

34 *Estimation of Stomach Functioning. (Ueber die funktionelle Magenuntersuchung.) A. Galambos.
35 **Indirect Estimation of Amount of Stomach Content. (Modification de la méthode Mathieu-Rémond.)* A. Laboulais and R. Goiffon.
36 *Idiopathic Enlargement of the Esophagus. (Speiseröhrenerweiterungen.) S. Mintz.
37 *Colitis from Mercurial Poisoning. (Experimentelle Beiträge zur Entstehung der Colitis mercurialis.) H. Cobliner.
38 Chronic Perisigmoiditis: Two Cases. M. Simmonds.

34. **Estimation of Gastric Functioning.**—The aim of Galambos' research was to compare the history of the case with the objective findings and with the findings with the test breakfast, striving to determine the differential value of the patient's story and the objective findings. He thus investigated eighty-six patients, giving 103 test breakfasts, and tabulates the findings under various headings. They show among other things that the various symptoms of something wrong in the stomach may be encountered in about the same ratio of cases with excessive, deficient or lacking gastric secretion and chronic gastritis; none is pathognomonic of any. He accepts, on the whole, Stiller's asthenia universalis, although the frequent exceptions to the rule may lead to erroneous conclusions. When the gastric secretion fluctuates irregularly from excess to deficiency, hysteria may be assumed, he declares, mentioning further that when blood is found in the stomach content in case of cancer, ulcer or erosion, the white leukocytes are generally numerous in it on account of the inflammatory conditions. If the proportions of red and white corpuscles are the same as in the circulating blood, then it is more probable that the bleeding has been caused by some injury from the stomach tube. He describes some cases to illustrate his points, urging that functional examination should never be omitted except in case of the well known *contra-indications* to the stomach tube, and especially not in nervous dyspepsia, on account of its suggestive action.

35. **Indirect Method of Estimating Amount of Stomach Content.**—Laboulais and Goiffon have modified the Mathieu method, as mentioned already in The Journal, April 2, 1910, page 1175. They use a titrated solution of sodium phosphate; after this is poured into the stomach and well mixed with its content by aspirating the fluid out and pouring it in again several times by raising and lowering the funnel, they withdraw some of the fluid and compare its concentration with that of the original, 1 to 1,000 phosphate solution. The method is *more exact the smaller the amount of stomach content.* After siphoning out a certain amount of stomach content, a given amount (q) of a solution of sodium phosphate of the concentration n is poured into the stomach and mixed *with its contents.* Some of the contents is then removed and its concentration estimated (n′), from which it is a simple matter to compute the amount of fluid in the stomach as it will equal n q — n′ q divided by n′.

36. **Idiopathic Enlargement of the Esophagus.**—Mintz gives the radiographs of several puzzling cases of idiopathic dilatation of the esophagus, comparing them with the history of the case and stating that in nearly every case there is a spastic stricture at the cardia, either primary or secondary, and that all trouble subsides as a rule when this stricture is conquered. Sedatives internally to control the stricture never benefited in his experience, nor galvanization, and recurrence followed generally in the cases in which Hacker's method of "sounding without end" was applied. Permanent recovery was obtained by Mikulicz in five out of six cases in which he *forcibly stretched the cardia with forceps introduced through* an opening into the stomach, and others have obtained equally favorable results with this measure and Reisinger from resection of the dilated portion. Temporary relief can be obtained by repeatedly rinsing out the dilated esophagus. Mintz is inclined to believe that many cases of supposed diverticulum in the esophagus in reality were merely a general enlargement. The various means of differentiation to date are not reliable, he says, and the Roentgen pictures only when taken with instantaneous exposures.

37. **Mercurial Colitis.**—A man of 52 was ordered to take pills of bichlorid of mercury for two weeks after an operation for glaucoma, but he continued to take the pills for four months, the daily dose being thus 0.01 gm., or 0.15 grains. Ulcerative colitis developed with diarrhea and the patient succumbed the fifth month to the results of perforation of an abscess in the rectum. There had not been any marked subjective disturbances at any time, no stomatitis, and all the organs appeared intact except the large intestine. Cobliner reports experimental research on mercurial poisoning which seems to show that the mercury circulates in the blood in the form of the albuminate and is eliminated into the intestine. A toxic action is evident when mercury ions are liberated, and incorporation of large amounts of salt splits off the ions and thus increases the toxicity of the mercury. The elimination of the mercury into the intestine can be promoted by irritating substances and reduced by sedatives.

48 *Chondrotomy for Funnel Breast. (Zur chirurgischen Behandlung der angeborenen Trichterbrust.) L. Meyer.

40. **Wassermann Reaction Not a Guide for Treatment of Syphilis.**—In order to ascertain the diagnostic reliability of the Wassermann reaction, Plehn has had the serum of 200 patients at the Urban general hospital repeatedly examined with the five various technics for the complement-deviation test. The vials with the serum were only numbered and the serologist knew nothing of the patients yielding the serum, not even whether they had a history of syphilis or not or had taken treatment. The results confirm the possibility that syphilis may become permanently cured with no or very slight treatment. Among the forty-two giving a positive Wassermann reaction repeatedly, nine had reached an advanced age without ever having had any manifestations of their syphilis after the very first, which was also the case in fourteen others who had received what would be regarded as very inadequate treatment; some in this group gave a positive, others a negative reaction. Neisser has stated this year that the spontaneous recovery of syphilis is an extremely rare occurrence, but Naunyn has asserted that it generally dies out of itself in most cases, even without treatment—although he is the last one to rely on this—and the experiences related here by Plehn demonstrate that a clinical cure with little if any treatment occurs oftener than is generally recognized. This fact explains the positive reactions obtained in so many persons who are supposed to be entirely free from a history of syphilis. On the other hand, the Wassermann reaction may become negative while florid manifestations of syphilis persist or develop afterward. The fact that the reaction has become negative does not therefore signify that the patient is actually cured; neither is it always possible, even with the most energetic treatment, to transform a positive into a negative reaction or prevent tardy syphilis of the nervous system, especially the parasyphilitic affections with and without a positive reaction. Plehn adds that the Wassermann reaction gives no information as to the infectiousness of the case. The reaction may persist positive for decades while the patient is free from the slightest clinical symptom; thus a positive reaction is no proof of the syphilitic nature of clinical manifestations developing during this period, which may or may not be of a syphilitic nature. On the other hand, a negative reaction is no proof that they are not syphilitic. Plehn reiterates that the Wassermann reaction is only one symptom of syphilis, and, like other symptoms, it may be present or not, and it may be encountered in conditions other than syphilis, as with neoplasms and lead colic. Plehn also has had occasion to deplore the depression produced by knowledge of a positive reaction in persons clinically normal. One young man recently committed suicide on this account and necropsy failed to disclose the slightest trace of syphilis. A syphilitic with a negative reaction may yet speedily die of brain syphilis, while others with positive reactions may live to be 77 and over without symptoms. He does not dispute the value of the test in certain dubious conditions, but regards the interpretation of the test as a matter involving great responsibility.

43. **Neurotropic Action of Salvarsan and Its Elimination.**—Fischer and Zernick report a case of polyneuritis and one of neuroretinitis developing in syphilitic women after injection of salvarsan. They also tabulate the findings in regard to the elimination of arsenic after intramuscular, subcutaneous or intravenous injection of salvarsan, showing that the elimination may continue for seven to twelve months and also that even after intravenous injection there may be storage of the arsenic in internal organs. The arsenic may be circulating in the blood, even when no traces of it can be detected in the urine.

47. **Sugar Solution in Diabetic Acidosis.**—Balint gives the sugar solution by proctoclysis so that absorption may be promoted and long continued. As a still further aid in this line he restricted the amount of calories in the diet during the two days of the proctoclysis, not over 700 or 800 calories being allowed, which included the 100 or 150 gm. of sugar in the rectal infusion. In some cases the acidosis ceased entirely or became strikingly reduced, the more so the longer the proctoclysis was kept up. The tolerance of the patients was much increased in every case and the acetonuria materially diminished for some time. He theorizes to explain this, ascribing the better utilization of sugar from the rectum to its passage at once into the general circulation instead of its being obliged to go around by way of the portal vein.

48. **Chondrotomy for Congenital Funnel Breast.**—Meyer reports the application of Freund's operation to relieve the depression of the lower sternal region which was so pronounced that as the boy grew he had not room to breathe and operative measures became imperative at the age of 16. About 2.5 cm. was resected from the second and third costal cartilages on the right side and the chest at once expanded and the lad has had no further trouble since. Meyer thinks that this chondrotomy should be applied to all abnormal conditions in the chest wall or spine causing interference with normal breathing.

Deutsche medizinische Wochenschrift, Berlin

August 17, XXXVII, No. 33, pp. 1505-1544

49 Criticism of Prevailing Theories in Regard to Anaphylaxis, Allergy and [illegible] General. (Ueberempfindlichkeit in [illegible]nschen.) A. Menzer.
50 Case of Fatal [illegible] F. Speyer.

57 Simplified Brandberger Apparatus for Determination of Albumin. (Neuer Apparat zur Brandbergschen Eiweissbestimmung nach Ameseder.) A. Dlabac.

51. **Dangers of Inflating the Stomach with Effervescing Mixture.**—Nieden protests against the recent statements of Stiller and Hoffmann in regard to the harmlessness of this measure as an aid in Roentgen examination. He reports a case of severe gastric hemorrhage induced by the procedure and cites two reported by Bardachzi and three with fatal outcome by Behrend and another by Leo. For Roentgen work he commends barium sulphate as effectual for shadow photography; it has been used at the Bonn medical clinic in thousands of cases without ever causing appreciable by-effects. It is important, however, to write out the name in full, adding "for internal administration," as the substitution of barium sulphite, for the sulphate, ordered as "barium sulph," proved fatal in a recent case in Freiburg.

52. **Rupture of Intestines and Bladder from Contusions.**—Gottschalk remarks that the outcome is growing better in these accidents as the first aid is becoming more intelligent. The duodenum was the viscus ruptured in all but one of his last series of fifteen cases (since 1901). Only one patient succumbed of the three with subcutaneous intraperitoneal rupture of the bladder and one of the five with extraperitoneal rupture. One of these patients was a healthy woman of 41 and the rupture occurred in a fall while dancing, her partner falling on her abdomen and rupturing the full bladder. At the operation a pedunculated fibrosarcoma, the shape and size of a kidney, was found in the omentum. It was readily removed, the findings indicating that the neoplasm had been attached to the bladder and had been torn away by the accident, the weakened wall of the bladder rupturing at this point.

53. **Appearance of Salvarsan in Milk.**—Bornstein found arsenic in the milk of women who had been treated with salvarsan and the arsenic was in a form identical with or closely allied to the composition of salvarsan. Experiments with a syphilitic infant fed with the milk of a goat which had received an intravenous injection of salvarsan proved disappointing. The goat milk contained much smaller proportions of arsenic than the specimens of human milk that had been examined.

59. **Stratification of Food in the Stomach.**—Kaufmann and Kienböck report study of this subject with the Roentgen rays on five healthy persons. The food spread out to form a sort of stratified shell, the food last eaten forming the kernel.

60. **Operative Treatment of Hemorrhoids.**—Dreesmann extols the advantages of two parallel incisions above and below the anus, leaving the latter intact. With a blunt instrument the skin is separated from the rectum and the hemorrhoids can thus be excised from without, leaving the mucosa intact. The incisions afford ample opportunity for inspection of the rectum and arresting hemorrhage. The details of the technic are shown in two illustrations as he has performed this operation on sixteen patients. The special advantages are that the wound being in a comparatively aseptic region rapidly heals by primary intention while there is no danger of stenosis later as the mucosa near the anus is not injured. For the same reason defecation is not painful.

62. **Tuberculosis of the Eyes.**—Lubowski expatiates on the necessity for a diagnostic injection of tuberculin for differentiation of dubious affections of the eyes, and describes several instances in which this alone cleared up the case. He deplores the dread among both patients and physicians of the tuberculin test; without it the patient is liable to drift from one physician to another, each diagnosing differently the eye trouble. It is important, he adds, to learn the numerous forms under which a tuberculous process may develop in the eye, and new cases should be described at length, so physicians may become familiar with them. Uveitis and scleritis are of tuberculous origin in the overwhelming majority of cases, and the tuberculous process may also manifest itself as an obstruction in the central artery of the retina with plastic iritis or neuroretinitis with central scotoma. He relates a case of the kind with complete recovery under tuberculin treatment. Probably the process developed behind the eyeball in the central canal of the optic nerve, and as it subsided under the tuberculin treatment functioning was restored without even any atrophic blanching of the optic nerve. In another case with hemorrhages in the vitreous body and obstruction of the central artery of the retina, the disturbances likewise all retrogressed completely under tuberculin treatment. The remarkably favorable outcome of the tuberculous thrombophlebitis is in striking contrast to the tendency to atrophy of the optic nerve left after traumatic lesions of the kind.

63. **Varicose Veins.**—Stephan has devised an elastic stocking which seems, he states, to control the circulation in the veins like the natural valves. The stocking is of linen with lengthwise strips of round wicking; it is laced only tight enough to compress the enlarged, not the normal veins. The intermittent compression thus exerted by the strips of soft wicking simulates the natural action of the valves.

64. **The Hematocrite in Estimation of Effect of Iron in Anemia.**—Schmincke measures the height of the mass of blood corpuscles in the graduated tube after centrifuging as a means of controlling the effect of treatment in anemic conditions.

67. **Specific Diagnosis of Tuberculosis.**—Jochmann urges that general practitioners should familiarize themselves with the tuberculin tests as their diagnostic importance cannot be overestimated, especially for early detection of tuberculosis. The special technic to be used depends on the circumstances of the case.

68. **Operative Treatment of Nephritis.**—Lichtenstern reports his experiences in this line, all justifying the conclusion that true Bright's disease is not amenable to surgical treatment but that operative measures are indicated for recurring rebellious unilateral renal hematuria, colics and anuria when they are the result of inflammatory processes. Recurring hemorrhage may be arrested by mere decapsulation and anuria by unilateral nephrotomy.

69. **Pneumococcus Meningitis.**—Kleinschmidt has encountered a number of cases of meningitis complicating pneumonia in the last six years, all fatal. Matthes reported four similar cases in 1908 except that there had been no pneumonia in three of them. Kleinschmidt here reports a case of pneumococcus meningitis following an infectious sore throat, the patient, a young merchant, recovering. Hexamethylenamin and pneumococcus serum had been administered, supplemented by lumbar puncture. Kleinschmidt thinks that this case suggests the advantage of giving hexamethylenamin in prophylaxis in epidemic meningitis, and also in croupous pneumonia, otitis media and injuries of the skull. Liebermeister has recently called attention to the frequent suppurative inflammation of the meninges found at necropsy after pneumonia, even when there had been no meningitic symptoms during life.

70. **Retention of Hydatidiform Mole.**—Mayer reports ten cases of this kind. In only one was the uterus very much enlarged; in the others the size corresponded to the period of the assumed pregnancy. In five cases there were atypical hemorrhages and blood-stained discharges; in two, small, tumor-like indurations in the uterus wall were palpable until after evacuation of the mole. The pathologic product had evidently been arrested in its growth but was not expelled and, although not causing special pathognomonic symptoms, it was seriously impairing the general health until it was mechanically removed the fourth or fifth month.

72. **Self-Treatment of Sciatica.**—Dannehl has the patient sit in a hot bath with the foot braced against the end wall of the tub, which he grasps above with both hands and pulls his trunk forward and over, thus stretching the nerve in the hip as he repeats the procedure. It is supplemented by light massage of the nerve trunk. The relaxation in the hot water facilitates both the stretching and the massage, and the patient's sensations are the best guide as to the intensity and duration of the procedures. They take thirty or forty minutes in all, and the water should be kept at about the same temperature, 38 C. (100.4 F.). At the close, cooler water may be poured over the body, avoiding the affected limb. The sound leg should not be braced. These baths should be taken every day or second day for months if necessary, supplemented by general hygienic measures. Dannehl has thus cured himself, by this means, of sciatica which had proved refractory for three years to all other measures, and the cure has been complete during the two years since.

75. **Labor an Anaphylactic Process.**—Sauerbruch and Heyde recently reported experiments with a gravid and non-gravid rat sutured together in parabiosis. The gravidity did not seem to be affected and both animals apparently throve until, a few hours before the gravid animal cast its young, the other suddenly developed serious symptoms, apathy or tetanic cramps or spasms resembling those of uremia. These experiments suggested that the fetal serum had acquired toxic properties which induced the disturbance resulting in expulsion of the contents of the uterus, and recent experiences here reported by von der Heide apparently confirm this assumption. Immediately after birth of a child and severing the cord the reserve placental blood from it was set aside to clot. He then injected 17.5 c.c. of this fetal serum in a young woman supposed to be at term and labor commenced in three hours. A similar result followed in three other women at or approaching term, and then in six cases in which labor had commenced but the labor pains had stopped, he injected 5 or 10 c.c. and labor started up again in a few minutes to one or two hours. One of these patients was a primipara of 30 and the period of dilatation had extended over days without labor pains, but they commenced two and a half hours after injection of 4 c.c. of the fetal serum and kept up for four hours, then ceased until the next day when they recommenced, with speedy delivery. He reports in all twenty-six pregnant women thus treated with fetal serum, the results demonstrating, he states, that not only is labor to be regarded as an anaphylactic phenomenon, due to the action of the alien albumin in the fetal serum, but that fetal serum is an effectual means to promote the contractions of the uterus in case of inefficient labor pains, either primary or secondary. He adds that injection of gradually increasing amounts of the fetal serum—on the principle of tuberculin treatment—might habituate the woman to the alien albumin so that anaphylaxis would not develop and she might carry the child over term. Injection of the fetal serum into non-pregnant women was not followed by any appreciable phenomena, seeming entirely inert.

76. **The Peroneal Nerve Phenomenon.**—Hyperexcitability of the peroneal (external popliteal) nerve was found constantly by Lust in the seventy-six children with spasmophilia examined, while the facialis phenomenon occurred only in 43.4 per cent. of the children although they all presented unmistakable signs of tetany. Holding the child's leg in his left hand he taps with a percussion hammer the external popliteal nerve near or just below the head of the fibula; if the nerve is unduly excitable, this induces transient abduction with dorsal flexion of the foot.

80. **Experimental Production of Malformations of the Eyes and Cataract.**—Pagenstecher fed gravid rabbits and guinea-pigs with naphthalin and there were malformations in the eyes in 50 per cent. of the rabbits in the following litters and in 33 per cent. of the guinea-pigs. The malformations included numbers of congenital cataracts. This experimental research proves the possibility of a toxic origin for cataract and that malformations are not necessarily due to an anomaly in the germ.

82. **After-History of Tuberculous Patients Treated in Sanatoriums.**—The statistics given in this article were cited recently in the Berlin Letter in The Journal, September 9, page 911. It rarely occurs that nearly three thousand patients can thus be kept under observation for so many years, while the conclusions are valuable as the material is so uniform, the patients all belonging to the wage-earning classes. It is certainly encouraging, Reiche remarks, to find that over 54 per cent. of the men and over 64 per cent. of the women given sanatorium treatment from seventeen to five years ago have regained full earning capacity, even although one-fifth required for this a second course and one-thirteenth a third. The data confirm the tendency of pulmonary tuberculosis to a long protracted course, long periods of latency and retrogressions.

83. **Anilin Poisoning.**—The patients were two boys one of whom had applied commercial anilin copiously to his hands in treatment of ulcerated chilblains; the other boy felt its toxic action only by inhalation as the two slept together in a defectively ventilated room. The anilin did not seem to have an inflammatory action on the tissues and the chilblains healed under it, but the general symptoms were severe and there was a bluish gray discoloration of the nails, gums, etc. Both boys were found unconscious but the one who had only inhaled the anilin had recovered the next morning, while the other was still too weak to stand by the ninth day, but then gradually recuperated.

88. **Peptic Ulceration in Esophagus, Stomach and Duodenum.**—Gruber tabulates the details of 170 cases of peptic ulceration or erosions found at 4,208 necropsies; 4 per cent. of the cadavers that reach the dissecting room at Munich thus have signs of peptic ulceration. In only eighteen of the 115 cases of actual ulcers had the affection been diagnosed during life. In fully 61 per cent. of the total 170 cases of peptic lesions morbid changes were found in the heart or vessels. The number of cases in all the various age decades ranged from sixteen to thirty-three except the small number of four between the ages of 10 and 20 and of seven between 80 and 90. Seventeen were in children under 10. In 14 per cent. of the cases the death was due to perforation and in 6 per cent. to hemorrhage from the lesion. Cancer was evident in 139 of the cases, but a connection with a preceding peptic erosion or ulcer was traceable in only 5.2 per cent. Gruber further tabulates all similar statistics that he has found on record in various countries; according to them peptic lesions were found in from 0.1 to 8.32 per cent. of the total necropsies. The higher figures are all from before 1880. No difference between the sexes is apparent from the tables, while the causal influence of cardiovascular disease seems evident. He urges all pathologic anatomists to seek for peptic ulcerations, erosions or scars at all necropsies as important general laws may possibly be learned from comparison of such data.

94 Vaccine Therapy in North America. C. T. Noeggerath.
95 *Fatal Naphthalin Poisoning. S. Prochownik.

89. **Tuberculin Treatment in General Practice.**—Meyer warns that tuberculin treatment may do harm if the dosage is too small as well as when the dosage is too large. It should be regarded as only one factor in treatment of tuberculosis, but is especially indicated for pronounced toxic symptoms such as palpitation of the heart, sweats, gastric disturbances, swelling of the thyroid and slight subfebrile temperature, also in extensive glandular and in open bone affections, combined with surgical measures. Hysteric patients do not take tuberculin treatment at all well. and it is contra-indicated when there is much fever, or pulmonary tuberculosis is rapidly progressive and complicated by mixed infection, epilepsy, severe neurasthenia or heart disease.

90 and 91. **Heubner's Warning Against Maretin.**—As Dreser's pharmacologic research was the basis for the production of maretin, he takes exception to Heubner's warning in regard to its toxic effect on the blood (given in full in The Journal, July 15, 1911: page 256). Dreser rejoins that phenacetin from this hypercritical point of view is also a poison for the blood, Krönig having reported in 1895 a case of fatal changes in the blood after a dose of 1 gm. (15 grains) of phenacetin, and yet no one hesitates to use phenacetin on this account.

Heubner replies to his statements in detail, saying in regard to phenacetin that the number of known cases of injury of the blood from it is negligibly small during the twenty-five years it has been in use in comparison with the number of cases of injury from maretin soon after its introduction. He reiterates that the continued use of maretin is liable to induce anemia even in the ordinary doses, and as an antipyretic action can be obtained with more harmless drugs, there is no reason for its use, certainly not over long periods.

93. **Treatment of Fracture of the Upper Arm in Infants.**—The usual splints used for this purpose hamper the movements of the thorax walls, and Göppert recommends a wire frame of triangular shape, padded at the angles, which fit into the axilla and elbow of the child and hold the arm away from the chest.

95. **Fatal Naphthalin Poisoning.**—The naphthalin had been ordered to expel thread-worms, and was given in ten powders of 0.25 gm. (about 4 grains) each, four a day for two days and then followed with castor oil. The child, a boy of 6, died with symptoms of naphthalin poisoning the third day, after having taken 1.75 gm. in all in two days. Lewin has also reported a fatality from this cause. It is possible that the castor oil dissolved the drug and thus an unusually large amount was absorbed.

Therapie der Gegenwart, Berlin

August, LII, No. 8, pp. 337-384

96 *Rhizotomy for Tabetic Gastric Crises. (Operative Behand- [illegible] n durch Resektion hinterer Dorsal- [illegible]
97 *Ve[illegible] in Diet for Diabetics. H. Strauss.
98 *Kuhn's Suction Mask in General Practice. (Ueber die Lungensaugmaske aus der Praxis.) P. Seebens.
99 *Diatheses in Children. (Ueber kombinierte Krankheitsbereitschaften oder Diathesen im Kindesalter.) M. Pfaundler. Commenced in No. 7.

96. **Rhizotomy for Tabetic Gastric Crises.**—Foerster reviews his experience with resection of the posterior spinal nerve roots in cases of tabes with gastric crises of such extreme intensity that the inanition and morphin poisoning were driving the patient into the grave and all other measures had failed to relieve. Only under these conditions does he consider operative treatment. The aim is to resect the sensory gastro-intestinal fibers of the sympathetic nerve, and this may require resection of the roots from the twelfth to the fifth dorsal or even higher; the few failures in the twenty-eight cases on record to date were undoubtedly due to the fact that too few roots were resected. It may be possible to determine beforehand, he says, exactly the roots requiring resection by careful study of the location of the pains and localization of the superficial hyperesthetic zones. Guleke found in one case that the crises recurred after resection of the seventh to the ninth roots but then vanished permanently when the tenth and eleventh roots were further resected. There is always a possibility that the crises may be due to the vagus or to direct irritation of the vomiting center in the medulla oblongata, in which case rhizotomy of course would not relieve. There have been only three deaths from the intervention although the patients were all extremely debilitated and their resisting powers at a low ebb from morphin addiction. Paraplegia of the legs, paralysis of the bladder with cystitis, and pains in the legs have followed the operation in a few instances, but proved transient except in Nonne's case in which the paraplegia of the legs seems to be permanent. These troubles are probably the result of operative injury of the spinal cord or of leakage of blood into the dural sac below or possibly of the draining away of the spinal fluid from the dural sac during the operation and afterward if the pelvis is raised. If the blood-supply of the spinal cord is interfered with, paralysis may likewise result. Another transient symptom is a certain atony of the abdominal walls with more or less meteorism. Many of the patients have been restored to comparative health and enabled to return to business.

97. **Advantages of Vegetables Rich in Inulin in Diabetes.**—Strauss has given with much benefit pure inulin in two cases of diabetes, and urges the addition of vegetables rich in inulin to the diet of diabetics, especially artichokes, dandelion, the black roots of viper's grass, an edible species of *Scorzonera*, and *Helianthus macrophyllus*, of the sunflower family, all of which will repay cultivation and, as a source of inulin, prove useful in antidiabetes diets. The absorption of the inulin proceeds naturally more slowly from the ingested vegetables than when it is given isolated, which is a distinct advantage.

98. **The Suction Mask in General Practice.**—Seebens states that Kuhn calls the mask by this name as it sucks up the diaphragm by restricting the intake of air while it allows expiration to proceed unhindered. During inspiration the diaphragm, the blood and the lymph are all sucked up into the thorax, the main effect of the mask being to induce hyperemia in the organs in the chest. By sucking the blood into the chest it reduces the blood-pressure in the brain and is thus useful in insomnia while the hyperemia in the lungs has a curative influence on lung and heart disease and in all forms of anemia, as also in bronchial asthma, emphysema and bronchitis, and, by its influence on sleeplessness, in neurasthenia. Seebens has applied the mask in thirty cases of various affections and with benefit in all, no by-effects being observed in any instance. He urges general practitioners to familiarize themselves with the advantages of this inexpensive and harmless method, warning that charlatans will soon be taking it up if the profession neglects it. (The principles involved were described in The Journal, Oct. 15, 1910, page 1421). Some fear that the mask may induce hemoptysis but Senator commends it directly for hemoptysis and Kuhn has never had hemorrhage from the lungs in all his experience with the mask.

99. **Diatheses in Children.**—Pfaundler regards the neurolymphatic tendency, the exudative diathesis, as the soil on which "scrofula" develops, and lays great stress on preventive hygiene, a climate which permits constant out-of-door life, companionship with children of the same age, and a diet which excludes more or less completely all animal food, especially milk, cream, butter and eggs, and also sugar. He has often found it possible to cure anorexia by forcing food on the child, giving it by spoonfuls, coaxing, threatening and rewarding the child for eating for a time and then suddenly ceasing this and leaving the child alone. He will not care for food at first but finally clamors for it. Or a meal may be skipped entirely, or the child kept waiting long at table before it is served, on one pretext or another, until it becomes extremely impatient for its food which it then eats with appetite. Children often refuse to eat vegetables, as they prefer other foods, but when milk and other animal food is denied them, they are forced to fall back on the vegetables which they soon take with relish if palatably prepared. The practitioner who instils these hygienic principles may be called a "turnip doctor," and parents may be dissatisfied with his directions, the public still having the medieval conception that drugging is all there is to therapeutics, but the physician must not swerve from his convictions, and the final outcome of the case will be his reward.

104 *Physical Symptoms of Mitral Insufficiency. L. Kürt.
105 Technic for Bacteriologic Diagnosis of Cholera. A. Weisskopf.
106 *Optic Neuritis with Exanthematous Typhus. V. Arnold.

100. **Auto-Intoxication with Acids.**—Porges is assistant at von Noorden's clinic at Vienna, where the subject of acid auto-intoxication has been especially studied. He reviews the various forms of intoxication and the various acids involved, as well as the various factors responsible for the accumulation of acid. The latter may include a deficiency of alkalies or insufficiency of the organs whose task is to eliminate the acid, as well as over-accumulation of the acid. Acidosis is a more common occurrence than has been hitherto recognized, he declares, and it has one pathognomonic sign, namely, increased functioning of the lungs, hyperpnea, the lungs drawing in more breath at each inhalation or the respiration becoming more frequent. Recent research has shown

that the respiration is controlled by the acidity of the blood, the respiration center being peculiarly sensitive to acids. It is probable, he declares further, that the respiration is a means of regulating the acidity of the blood; the lungs by eliminating carbonic acid thus strive to maintain the balance of acidity by throwing off the excess of acid in this way. The increased respiration is thus a sign that the organism is striving to compensate commencing acid intoxication by throwing off increased amounts of carbonic acid. The hyperpnea has the further consequence that the tension of carbonic acid in the blood declines, and this, too, may prove useful in early detection of acidosis. The abstract research recorded thus permits greater certainty in our therapeutic measures. When the physician is confronted with a patient in coma and there are no anamnesic data, and nothing to explain the coma can be discovered on examination of the patient, the presence of hyperpnea discloses that the coma is due to acid intoxication, and hence that alkalies are indicated. On the other hand, the lack of excessive functioning on the part of the lungs may serve to exclude diabetic coma and coma from any acidosis. Meat and other protein foods do not induce acid intoxication but they contribute to acidosis and hence should be restricted when there are other causes suggesting the possibility of impending acidosis, as in certain forms of nephritis and in diabetes. The favorable action of this has long been confirmed by experience and the research reported explains its mechanism from another standpoint. The findings from the research enable us also to refrain from inflicting unnecessary dietetic restrictions on our patients, as the organism has means at its disposal under ordinary conditions to render harmless the acid elements of meat.

101. **Rhizotomy.**—Stiefler reports a case of severe spastic paralysis in a boy of 12 in which he resected the posterior spinal roots according to Foerster's technic with excellent results. It is the forty-first case on record, he says, in which this technic has been applied in Little's disease and successfully in thirty-one; no benefit was apparent in five cases and four of the patients succumbed, one in an epileptic seizure, another from postoperative pneumonia and another from an iodin dermatitis. In the present case the patient is now able to sit erect and walk with the aid of a walking stool. He reports further a case of intolerable gastric crises in a tabetic man of 49 on whom the same operation was performed, adding that in the twenty-six similar cases on record a cure was realized in twelve cases. Great benefit was also apparent in this case, the gastric crises not recurring and the general health showing marked progressive improvement, but the patient died suddenly the seventh day. Necropsy indicated that the fatality was the result of bulbar paralysis and that the operation need not be incriminated, the tabetic lesions in the medulla oblongata amply sufficing to explain the sudden death.

104. **The Symptomatology of Mitral Insufficiency.**—Kürt writes from von Neusser's clinic at Vienna to discuss the physical signs and symptoms of mitral insufficiency at different ages and different stages of the disease and the explanation of their mechanism. He warns that accidental murmurs may be observed in early childhood and lead to much diagnostic confusion. Organic systolic murmurs in children are liable to be more pronounced in the dorsal decubitus. In adults he has found the systolic murmur over the apex more pronounced with the patient lying on the left side. To date he knows of no decisive means of differentiating organic from accidental murmurs. Some instances are cited to show the advantages of indirect palpation in certain dubious cases, and the diagnostic importance of an unusually pronounced pulsation in the chest wall outside of the apex, indicating that the left ventricle is lying closer to the wall than normal and over a larger area, although there may be nothing else to indicate that it is enlarged.

106. **Optic Neuritis with Exanthematous Typhus.**—Arnold states that since he has made a practice of examining the eyes of patients with spotted fever he has found traces of optic neuritis quite common. It was pronounced in eight and mild in two among his fourteen patients with this disease, but none complained of visual disturbances. The neuritis persisted longer than any other symptom but finally retrogressed completely in nearly all, but in a few there are signs of incipient atrophy of the nerve. He adds that he has encountered optic neuritis in no other infectious disease except meningitis, in which he has invariably found it or witnessed its development. He has never found it in typhoid fever and Groenouw was able to find only twenty cases in the literature of optic neuritis in typhoid fever. The discovery of an optic neuritis may therefore turn the scale in favor of exanthematous typhus in dubious cases.

114 Leverage Extension in Treatment of Fractures. (Hebelextension.) C. Deutschländer.

107. **The Two-Route Method of Treating Local Lesions.**—Reuterskiöld reports favorable experiences with Pfannenstill's method of acting on lesions by two routes: potassium iodid taken internally and ozone or hydrogen dioxid applied externally. (It was described in THE JOURNAL, July 16, 1910, p. 264.) About 3 gm. of potassium iodid are taken during the day and the lesion is kept moistened with hydrogen dioxid. Reuterskiöld has found it convenient to use two vials connected with a wick, the upper vial containing the hydrogen dioxid which drains away into the lower vial through the wick, the wick being bent in the middle and this fold being introduced into the depths of the lesion. The solution should give an acid reaction and for this he adds 0.25 to 1 per cent. acetic acid, using a 3 to 1 per cent. concentration of hydrogen dioxid.

108. **Operative Treatment of Tabes.**—Schüssler states that in sixty cases of lumbar tabes he has exposed the sciatic nerve and found it invariably in a focus of perineuritis. This alone is sufficient to explain the pains in lumbar tabes; both the gastric crises and visceral symptoms may be regarded as reflex neuroses, originating in the nervi nervorum of the inflamed neurilemma. The disturbances are generally the result of adhesions, and by slitting the neurilemma and releasing the nerve from the adhesions, the pains are arrested. When the left forefinger is worked under the nerve and lifts it, the adhesions can be heard tearing. Six weeks of after-treatment should follow this neurolysis procedure. One man of 40 with severe tabetic crises and symptoms has been free from pain since it was applied in 1910.

122 Improved Management of Umbilical Cord. (Methode, die Nabelabklemmung mit der Unterbindung zu kombinieren.) B. H. Jägerroos.

119. **Meningitis Following Spinal Anesthesia.**—A supposedly healthy woman developed symptoms of meningitis after spinal anesthesia. The Wassermann reaction proved positive and under salvarsan the symptoms promptly subsided. Linzenmeier remarks that the experience suggests special caution with spinal anesthesia on suspicion of syphilis, and also the necessity for tentative specific treatment if symptoms of meningitis follow the anesthesia and persist.

120. **Resection of Corpus Uteri in Tuberculous Pregnant Women.**—Bardeleben has been shocked at the high mortality in tuberculous women who become pregnant even when abortion is induced, 25 and 58.3 per cent. of his fifty patients in the first and second stages of pulmonary tuberculosis dying in less than sixteen months after the abortion. After trials of various supplementary operations, he reports favorable results after systematic excision of the corpus to supplement the abortion. The mortality has dropped to 5.6 per cent. with this technic, which he describes in detail with illustrations. In forty cases, the women less than four months pregnant, he operated by the vaginal route and in the eight others by the abdominal. The operation required only twenty to thirty-five minutes: hemorrhage was slight. Enough functioning corpus tissue is left to prevent disturbances later, while the site of the placenta is removed and the stumps of the adnexa are ligated outside the peritoneum. None of the patients died within sixteen months of the pregnancy and menstruation is not interfered with except that the menstrual hemorrhages are less copious. The operation aims to free the woman of the last trace of her gestation while preventing further conception.

129 *Present Status of Pellagra Question. (Nuove vedute eziologiche e nuove critiche a proposito della pellagra.) E. Bertarelli.

125. **Treatment of Hemorrhoids.**—Baroni has found that mere forcible extensive dilatation of the anus has sometimes been sufficient to break up the vicious circle maintaining the hemorrhoids, and in any event is a powerful factor in the cure. When further measures are required, he seizes the tip of each hemorrhoid with forceps and pulls it out as long as possible, ligating it at the base, passing the needle through the base to prevent its slipping. There is no danger of tardy hemorrhage with this technic nor of stenosis as the mucosa is left intact between each nodule as they are thermocauterized.

129. **Pellagra.**—Bertarelli reviews the various theories in regard to the origin of pellagra to date. While he thinks that there is no positive evidence to explain its origin, yet the probabilities are in favor of its being an infectious disease due to a protozoon or some microorganism of similar biologic characteristics, the corn theory not having stood the test of time. The principal argument against the corn theory is that the rigorous measures in regard to the corn harvest and corn as a foodstuff, introduced in prophylaxis of pellagra by the Italian government, have given such mediocre results. The number of cases of pellagra have diminished but by no means in proportion to the extent of these measures and the strictness of their enforcement.

THE RELATIONSHIP BETWEEN DISEASES OF THE EAR AND THOSE OF THE EYE*

DUNBAR ROY, A.B., M.D.
ATLANTA, GA.

I must felicitate the members of this Section on the excellency of our program for this meeting, giving due credit to our worthy Secretary, whose ability in this direction is certainly most commendable. It leads me to urge the adoption of the suggestion from one of our former Chairmen as to the advisability of retaining, for several years, the same man in this office and thus assuring the Section the prospects of a well-arranged and scientific program.

This is the first time that we have met in this far-famed western municipality and, while the workers in oto-laryngology of this Section are known to us through medical literature, we are glad to-day to recognize the imprint of their personality.

It has been a time-honored custom for your Chairman to deliver an address at the opening of our Section meetings, but in the last few years such officers have handled with eminent literary thoroughness every phase of the history and progress of the oto-laryngologic work, so that there is little left in the field which can be considered otherwise than personal views. For some time past much has been written concerning the relationship between diseases of the eye and the nasal cavities with their accessory sinuses, but with the exception of the ophthalmoscopic appearances of the optic disk in cases of suspected brain abscess from middle ear suppuration and the question of nystagmus in labyrinthine involvement, the articles which have appeared in our medical literature on the relationship between diseases of the eye and ear have been quite limited in number. The advanced conservative radical treatment of diseases of the nasal cavities has certainly had a very marked influence in lessening many diseased conditions of the eye, notably that of the lacrimal apparatus, for where we were accustomed to see dozens of patients sitting around our clinic with probes in their lacrimal ducts, now we see but half the number. This is attributed to the attempt being made to give the nasal cavities freer ventilation by the removal of all obstructions.

On the other hand, with the exception of a few scattered articles, notably those of Moos, Rohrer, Rollet and Park Lewis, there have been but few clinical presentations of the relationship between diseases of the eye and those of the ear.

It has only been within the last few years that the teaching of otology in our medical schools has been given an independent chair or an association with rhinolaryngology, as previous to this time it was quite universally associated with the chair of ophthalmology, especially in the smaller medical schools, and even to-day such exists in some of the medical colleges of this country. While such a relationship seems anomalous in the light of our present studies in oto-laryngology, there nevertheless exist some clinico-pathologic grounds for this condition, as is exemplified by the reports from those whose daily practice embraces diseases of both the eye and the ear.

Some vague suggestions have been heard of preferring to limit the chairmanship of this Section, as in other Sections, to men whose practice lies exclusively in that domain for which the Section stands. In other words the Chairman of this Section should be a man whose work is exclusively oto-laryngologic, just as the Chairman of the Section on Ophthalmology should be one whose work is exclusively ophthalmologic. Such ideas to my mind would be detrimental to the best interest of our Section, for this national Association embraces in its membership those whose life work and practice are confined to the small as well as to the larger municipalities, and it is only in the largest cities that a man's clientele is sufficient to allow him to confine his practice to one single organ of the human body. Consequently if such a rule were adopted, our chairmen could only come from the largest cities, while the men from smaller places, doing equally as good work, would be considered ineligible. Such ideas may be very good in theory, but in practice they are certainly not to be commended, for at the present time there are few men doing ophthalmologic work who do not also embrace the oto-laryngologic in their practice, and vice versa this is true but to a smaller extent.

While it is a fact that the oto-laryngologist may work almost independently of the ophthalmologist the reverse is certainly not the case. as has been forcibly demonstrated during the last few years. No man can be a thorough ophthalmologist without having considerable knowledge of oto-laryngologic diseases. He who daily observes diseases of the eye, ear, nose and throat, who studies closely the correlationship of these organs with certain diseased manifestations in each and the end result of their treatment, is certainly more capable of making a correct diagnosis than the man who has to consult a colleague, who in turn only sees and draws conclusions from certain local appearances and who can never thoroughly imbibe the history of the case. Such pioneer workers in ophthalmology as Knapp, Greuning, Sattler, Kipp and others recognized this fact years ago and became thoroughly familiar at the same time with oto-laryngologic diseases. I hope, therefore, this Section will maintain broader views than that only men who practice exclusively oto-laryngology should be selected as its Chairmen.

---

* Chairman's address before the Section on Laryngology, Otology and Rhinology of the American Medical Association, at the Sixty-Second Annual Session, held at Los Angeles, June, 1911.

With this preface I wish to review in a very cursory manner the literature bearing on the relationship between diseases of the eye and the ear, and as I do not desire to occupy much time in this address the subject must of necessity be far from exhaustive.

When we recognize the fact that medical literature teaches us it was the ophthalmologist who first pointed out the presence of nystagmus in certain diseased conditions of the middle and internal ear, a subject which of late has occupied so much of the otologic discussions, it seems quite fitting that we should look for a moment into the pathologic relationship between these two organs. In taking up the literature of the subject, I have availed myself of all the writings at my command and have quoted freely from them, in order that we may clearly recognize the importance of workers in oto-laryngology being familiar with ophthalmology just as the reverse is even more to be desired.

I. AFFECTIONS OF THE EYES WHICH HAVE BEEN CONSIDERED THE CAUSE OF CERTAIN AURAL DISTURBANCES

In 1898, Rohrer, in a very exhaustive article on this subject, urged a very ingenious embryologic and histologic relationship between the eyeball and middle ear. He makes the cornea homologous with the promontory and the pupil with the labyrinthine windows; the conjunctival sac with the middle ear and the nasal duct with the tuba Eustachii; the tear glands with the acinous glands of the tube, the drum membrane homologous with the membranous portion of the eyelids.

Ostmann, in 1897, called attention to the fact that the eye is much more commonly affected by the ear than vice versa. Affections between these organs may be induced through reflex radiation and combined stimulation of the motor fibers or indirectly through otitic diseases of the brain and cerebral meninges. The nerve tracts which permit these relations between the eye and the ear according to this author are—the trigeminal, facial and acoustic nerves, the latter giving rise to a great variety of reflex effects on the eye according to the involvement of the vestibular branch (static function) or the true auditory nerve, the cochlear branch. Both the eye and the ear are abundantly supplied with sensory fibers from the trigeminus, accounting for the pain in the eye that is felt in severe middle ear suppuration. The facial nerve establishes a communication between the eye and the ear by enervating the stapedius muscle on the one hand, and the orbicularis palpebrarum on the other. It is for this reason that a deep, humming sound in the ear is perceived on tightly shutting the eyelids, which is interpreted as a muscular bruit originating from the stapedius.

As a corollary to this, Moos has reported a case of a woman 60 years old, who had a ringing in her left ear whenever she put on her nose glasses; when she removed them the noise disappeared. This was attributed to a reflex spasm of the stapedius muscle.

Dr. Geo. Stevens, in 1881, before the International Medical Congress, reported several very interesting cases in which aural tinnitus was diagnosed as due to a muscular imbalance in the eyes, relieved by graduated tenotomies of certain extra-ocular muscles, and Dr. Theobald, in 1909, before the Section on Ophthalmology of this Association, reported four cases, besides having observed many others where certain aural disturbances such as tinnitus, muffled and stuffy sounds, and even vertigo were entirely relieved by the correction of definite eye-strains. I myself had been skeptical of this latter statement, but only within the last few months a case came under my own personal observation where severe tinnitus aurium was relieved by the proper correction of a refractive error.

A case has also been reported by Rollet in which a tinnitus was produced whenever the ophthalmoscope was used in the eye on the same side and which ceased immediately after.

D'Arsonval has reported deafness for two hours following the looking at a Voltas light for a few minutes and he believes that it was due to the irritation produced by the ultra violet rays.

Moos, in 1898, reported a case of bilateral panophthalmitis following bilateral cataract extraction which was followed by meningitis and finally by complete bilateral deafness—a case of direct extension of the pathologic process rather than reflex radiation.

De Capdeville has reported two very unique and interesting cases: The first was in a blacksmith into whose left eye had been driven an iron chip. The latter produced considerable traumatism, but was finally extracted. Severe inflammation followed, however, and on the twentieth day after the accident, the left ear began to be affected with tinnitus and deafness. Nothing abnormal could be discovered about the ear. Finally the eye was enucleated and on the next day all subjective phenomena in the ear had disappeared and the hearing became normal. In the second case he reported that of a woman who four months after a cataract extraction showed some ciliary injection and later severe irido-cyclitis with supraorbital pains. Following a subsidence of the acute pain, the ear on the same side became affected with tinnitus and diminution of hearing, so much so that finally the hearing disappeared entirely and the eye symptoms continued. Enucleation was eventually performed which relieved the tinnitus and vertigo, but the hearing remained defective.

To these cases can be added those of Dransart: In the first case a tinman, 28 years old, was injured in the left eye by a chip of iron. This latter was removed, but traumatic changes were left. Later the patient received a blow in the right eye and this was followed by deafness in the right ear. Later an iridectomy was made in the right eye which was followed by improved hearing on the same side.

The sixth case reported is interesting and even startling: A journalist, 56 years old, had entropion of the right lower lid. At the request of the patient this was operated on with good results. Following this, the patient, who had been deaf since his eighth year, reported that he could hear perfectly well.

Bouchut relates the case of a young man who was struck by a ball over the right eye, producing a contusion and finally dimness of vision. This was followed by almost complete deafness in the corresponding ear. These cases certainly seem unique and must be considered in the light of severe reflex irritation rather than through any direct pathologic relationship.

With the exception of the case referred to, I have never seen any other in which aural disturbances could be considered as due to pathologic conditions of the eye, but we are compelled to recognize the fact that such exist, for they have been reported by competent observers.

II. AFFECTIONS OF THE EAR WHICH HAVE BEEN ATTRIBUTED AS THE CAUSE OF CERTAIN OCULAR DISTURBANCES

Here we realize that every ophthalmologist should be familiar with diseases of the ear if he wishes to be thoroughly competent to make a complete diagnosis. This subject is too extensive to be even partially handled in an address like this, and in making a review of the literature embracing this point I shall be able to barely mention its salient features.

During the last two or three years our medical journals have been filled with clinical reports and discussions on labyrinthine diseases of the internal ear and especially concerning the question of nystagmus as a means of diagnosis. No one could underestimate the wonderful scientific work which has been done by Barany and others as an aid to the differential diagnosis of internal ear diseases and no one knows better than the ophthalmologist the difficulty and uncertainty which surrounds the question of nystagmus and how frequently it can be made manifest in diseases other than those of the internal ear. The aurist and ophthalmologist must work together if this symptom is to be recognized as one of positive value; this again teaches us that it is of distinct assistance for the aurist to be a good ophthalmologist.

The effect of labyrinthine changes on the eye and that of brain abscess, has been too extensively considered and discussed for further comment in this address. Consequently I shall exclude these questions and only mention such as are not so familiar in aural and ophthalmologic literature.

Affections of the ear, especially middle ear diseases, have long been known as capable of giving rise to ocular paralyses. In the majority of cases the paralysis involves the external ocular muscles on the side corresponding to the otitis and it appears independently of meningitic symptoms.

The study of the anatomico-physiologic relations between the organ of hearing and that of sight readily explains such a relationship of the ear to the ocular apparatus, but the difficulty begins when we try to interpret the symptoms and to establish the pathogenesis of ocular palsies of otitic origin. According to Urbantschitsch, they were first vaguely considered as reflex disturbances. Later under the influence of the microbic theories, according to Berger, they were attributed to infectious neuritis due to toxins produced by ear infection. Numerous cases have been observed, however, in which the paralysis very probably owes its origin to the direct propagation of an infectious lesion—Gradenigo, Terson and others.

Of course, these remarks are not meant to cover the grave cases of otitic suppuration, giving rise to severe cerebral complications (abscess of the brain, meningitis, intracranial thrombo-phlebitis) in which the infectious origin cannot be doubted. The oculomotor paralysis in these cases is merely a side phenomenon of secondary importance.

The frequent occurrence of paralysis of the sixth pair in affections of the middle ear is accounted for according to most authors by the special relations between otitis and this nerve through the carotid canal, while Perkins believes that the majority of these cases are due to osteitis of the petrous tip.

A series of noteworthy contributions to this subject was published by P. Bonner who, in 1893, called attention to the labyrinthine oculomotor connections and gave as labyrinthine symptoms the oculomotor disturbances through radiation, such as strabismus, diplopia, miosis, etc. Bonner, in the same year, also reported an observation on a patient who suffered repeatedly from disturbances of accommodation in the right eye after strong injection into the right ear for the removal of cerumen and even became presbyopic for several hours, all of which disappeared with the removal of the cerumen. While the occurrence of reflex paralysis seems to have been demonstrated clinically as well as experimentally for the external recti of the eye, the problem is not so clear in cases of the other muscles.

De Lapersonne observed a case of paralysis of the superior oblique which he thinks referable to the same origin. Not only the extrinsic muscles of the eye, but also the intrinsic muscle tissue may present reflex paralysis in consequence of a lesion. Paralysis of accommodation has been reported (Boerne Bettman) as also mydriasis and myosis. Such an occurrence does not even seem to require a serious reaction on the internal ear such as takes place in the presence of vertigo, severe pain, tinnitus and deafness. A weak irritation sometimes suffices and the starting point may be the external ear. Sabrazes reported a case on unilateral mydriasis caused by the presence of a fragment of barley in the internal auditory canal. An analogous case was published by Brandelier; the foreign body was cerumen around a glass bead.

According to Moos, an infectious process of the ear may be propagated from the petrous bone to the meninges, along the trigeminus as far as the Gasserian ganglion, and according to Wiethe, by way of the tympanic and pterygoid venous plexus as far as the ophthalmic vein, where it gives rise to an orbital abscess.

Urbantschitsch has reported a case where dilatation of the pupil was induced in a patient by the rapid change of air pressure in the tympanic cavity, and cases where a suppurative process of the middle ear has influenced the dilatation and contraction of the pupil have been reported by Moos, Schwartze, Gelle and Gervaïs. Certain observations as to reflex action on the muscles of the eye-lid have been made.

In a case of Desterne a single air douche of the middle ear was followed by the cure of a twitching of the right eyelid which had persisted for over a year. Schwartze mentions the cure of a ptosis after the removal of an ear polyp. Blepharospasm due to the introduction of an ear speculum was noted by Buerkner, and Buzzard observed blepharospasm due to a plug of cerumen in the auditory meatus.

Ostmann, while making mention of these reported cases of seemingly reflex paralysis and spasm, does not believe in the reflex irritation theory, but thinks that such is rather due to intracranial complications. Kipp, as early as 1884, reported two cases of metastatic panophthalmia in connection with middle ear suppuration and this very observant ophthalmologist was one of the first men to call attention to the symptom of nystagmus in connection with severe middle ear diseases—a fact which should always be remembered in discussing the history of labyrinthine diseases.

In this connection it should also be mentioned that Kitamura has reported a case of metastatic ophthalmia as a sequel to sinus thrombosis. Urbantschitsch, in 1908, contributed a very long and exceedingly interesting article on "Subjective Acoustic Phenomena and Subjective Visual Concepts," in which he dealt with sensations of sound and color which accompany unconscious cerebration. Various color sensations may modify the subjective perception of musical composition. Simultaneous excitation of the two eyes by different colors produce changes in the subjective hearing which do not occur with one. I have a friend on whom certain high notes produced the sensation of violet and many such instances could be mentioned of this physico-psychic phenomenon.

I cannot close this paper without mentioning an article by Professor Peters of Rostock, who published in Vol. 36 of Knapp's *Archives of Ophthalmology* an article on miner's nystagmus in which he undertook to show that this condition could be well accounted for by the influence of the vestibular apparatus of the ear on the movements of the eye, particularly nystagmus. He shows good authority for such ideas as founded on the experiments of Breuer, Ewald and others. That nystagmus is produced through irritation of the semicircular canals is now fairly well established, as the number of cases reported in the last two years by otologists will testify; and the prominence of this symptom as shown by Barany and others as a diagnostic sign of vestibular irritation—Peters' argument—is by no means illogical and certainly opens a new field for further investigations.

In conclusion, let me urge otologists as well as ophthalmologists to bear in mind these relations of which I have spoken, for my own observation leads me to believe that many mistaken diagnoses have been made by not considering the interdependence of the various organs of the body.

THE LEUKOCYTOLOGY OF TYPHOIDAL DISEASES, AS A GROUP-PHENOMENON WITHIN THE TYPHOID-COLON FAMILY OF BACILLI (TYPHACEÆ)*

J. F. HULTGEN, M.D.
Pathologist to the Englewood Hospital
CHICAGO

Typhoid and paratyphoid bacilli, the bacillus of Gärtner, the paracolon, colon and dysentery bacilli belong to one family.[1] Botanically, they are branches of one tree. There are no permanent, fundamental, cultural[2] or morphologic differences between them.[3] The identification of a single member of this group by any special culture-medium has not been realized. The primordial kinship and common ancestry of these allied germs is demonstrable in many ways. It is only by acquired or biochemical properties that members of this group differ from each other. The Widal reaction, as Durham first showed, is only electively specific, not strictly so in the sense of Widal's and Buchner's words. The teaching of exclusive specificity in medicine produced not only passive, *laissez-faire* clinicians and therapeutic nihilists, but also a crop of specific public hygienists. Pasteur's conception of a specific pathogenic agent for infectious diseases shows the inspiration of a genius, Richet's anaphylaxis and Bordet-Gengou's complement deviation are of incontestable benefit to mankind, but somehow these several discoveries have not accomplished what they seemed to promise. The conditions under which a germ of a given group becomes pathogenic for man are as yet very obscure; even the rules of immunity as applied to anaphylaxis stand on their head.[4] It is certain that our reasoning on the ground of the strictly specific pathogenesis of germ diseases is too narrow. Anatomic and clinical phenomena do not justify the strict separation of typhoid and paratyphoid fevers.[5] Their epidemiology belongs together.[6]

I believe that the epidemiology of all infectious diseases, their morbidity and mortality statistics, their pathogenesis, their pathology, and clinical manifestations will be better understood when we shall study them collectively by groups, rather than individually. Just as in qualitative chemistry, there is shown in qualitative bacteriology[7] a distinct arrangement into botanical families. The law of periodicity of elements as propounded by Mendeleeff[8] in 1869 is applicable to the realm of microorganisms. Even now the laws of chemistry begin to dominate bacteremic processes.[9] That such reasoning is logical is proved by the following:

Germs, like chemical elements, can be arranged into definite groups, because, first, their individual members are morphologically similar; second, they feed or may eventually be made to feed[10] on the same culture-media; third, they show a distinct racial attitude toward oxygen and nitrogen; and fourth, their biochemic products bear plainly the stamp of family-reactions, as proved by Pfaundler's co-agglutinins, and by their leukocytic reactions. Andrewes[11] has found that guinea-pigs are co-sensitized toward paratyphoid germs and colon bacilli by previous injections of typhoid bacilli. From the standpoint of histochemistry and histopathology the classification of infectious diseases into groups suggests itself. The serum and tissue reactions of the typhoid-colon group, of the anaerobic intestinal flora, and of the streptopneumococcus family are group phenomena. The leukocytology of these infections furnishes the biochemical proof of the generic kinship between the members of these bacterial races. Clinically, this grouping of infectious diseases is very striking and, in my opinion, constitutes another proof of the existence in nature of the cyclic or periodic arrangemnt of germs — of living, organic molecules — parallel to that discovered by Mendeleef in regard to chemical elements. It is not unlikely that the teleological scheme of this grouping exists for the induction, maintenance and consumption of the circulation of elements within the human body. The generic, racial or electively specific activity of the typhoid-colon group is spent on the growth and the decay of the protein molecules in the intestines.[12]

As to whether infection and immunity in man show evidences of an evolutionary or mutating character of germs, and of their reactions on the host, I cannot discuss at this time. Suffice it, now, to take up the present status of pathogenesis, and clinical and epidemiologic significance of the leukocytology of typhoid and paratyphoid fevers.

My object in writing this article is, first, to enounce and promote the group study of typhoid infections;

second, to show why we should suspect and diagnose them earlier than hitherto; third, to discuss the part played by the tissue-cells in the production of group-characteristics versus the specific theory of one individual germ; and fourth, to revaluate the significance of the Widal reaction.

The study of the individual members of the typhoid, paratyphoid colon group has demonstrated a marked discrepancy between the morbidity and mortality statistics of these affections. Indeed, Hazen's[13] theorem of the Mills-Reinke phenomenon is an attempt to cover up this breach in the epidemiology of these water-borne diseases, the generic relation of which was recognized by a layman before clinicians thought of it. The classification of water-borne and food-borne diseases, however, should be based on clinical evidences mainly.[14] The early bacteriologic diagnosis serves essentially to identify the group to which the germ belongs,[15] cultural tests being insufficient and serologic reactions occurring late in the disease. In order to diagnosticate a case of typhoid or paratyphoid infection early we must suspect it earlier, that is, even before clinical evidences have become manifest. In typhoidal affections the preclinical symptoms consist in the bacillemia and the leukocytic changes, which, presupposedly, must have existed for some time, perhaps for two or three days, before the onset of any subjective symptoms. If at all applicable, the curative vaccine therapy[16] or the medical abortive treatment of typhoid fevers must be applied very early to induce bacteriolytic immunity, in view of the absence of antitoxic and phagocytic antibodies as observed by Vaughan and his school.[17] The end of the first week of typhoid fever is called the diagnostic stage by O. Naegeli.[18] It is then that the leukocyte counts are most valuable, as I have shown before.[19] The early stage of all typhoid infections is the most infectious, because the germs are very numerous in the circulating blood and excreta during the first stage of the disease.[20]

Typhoid bacillary sensitization is a protein poisoning. The manner of the intoxication, rather than its nature, determines the peculiar lymphoid tissue and leukocytic changes of typhoid fevers. The tissues furnish the characteristic reactions rather than the germ, and they do so *in accordance with the manner in which the alien protein is brought in contact with them.* This would account for the clinically polymorphous character of typhoidal and paratyphoid affections. Laurent[21] holds that the number of successive generations of bacilli decide on the severity of the infection. It is probable that the negative phase of antityphoid vaccination,[22] the negative phase of leukopoiesis in rabbits, as observed by Andrews, and the incubation of typhoid fevers in man are illustrations of one and the same process.

The revaluation of the Widal test is imperative. This reaction is less specific than formerly believed, but its scope is widening since Pfaundler's work. Its late appearance is its chief drawback, and, owing to the indefinite onset of the disease, an early Widal reaction should always be viewed with suspicion.[23] Its value as a means of group-diagnosis has increased, while in specific diagnosis it has admittedly lessened. The pre-Widal diagnosis of typhoidal diseases should be the rule, not the exception. Paratyphoid affections are seldom recognized in practice and are often classed as ptomain poisoning, gastric fever,[24] mucous gastritis[25] or walking typhoid fever. The existence of intermediate forms of the typhoid colon group, the insensible gradations from the bacillus of Eberth to the bacillus of Escherich, and the exceedingly important pathogenic, hematologic, epidemiologic and clinical characters, varying in crescendo or diminuendo with the distance of a given germ from the top or the foot of his family tree, is unfortunately but little known in medical books.

The incentive for this work grew on me in the course of the last six years, while making routine blood examinations on all of my patients. The value of careful hemanalyses[26] has been recognized by several authors, especially in differential diagnosis.[27] Other reasons impelling me in this line of investigation were the following considerations: Clinically, it is characteristic of the members of typhoid-colon dysentery group to produce ulcers, owing to the lymphotoxic effects of their poisons. While the ulcers of typhoidal and dysentery group show a distinctly segmental intestinal localization, the colon bacillus produces ulcers of the stomach (F. B. Turck), appendix and large bowel. The higher in the scale of this group a given bacillus is, the longer the incubation, the greater the crescendo of negative leukopoiesis, the more marked the immunity, the less the facultative saprophytism and the more pronounced the clinical condition known. I am referring to the bacillus of Eberth. With a preliminary generalizing survey of the typhoid-colon group it will be easier to understand the leukocytology of typhoid and paratyphoid fevers. The diagnostic and prognostic significance of complete successive blood-counts will then explain itself. It is to be hoped that cytology may clear a situation which has lasted for thirty years, and for which twenty years of humoral pathology have not accounted. Typhoid fever does not spontaneously occur in lower animals. The typhoid peritonitis of guinea-pigs is no parallel to typhoid fever in man.[28] Experimental bacteriology is of little use here. Combined bedside and leukocytic data furnish the safest basis for clinical reasoning and for a correct attitude toward the pathogenesis of infectious diseases. The leukocytology of typhoid and paratyphoid fevers is another proof for the distinct generic relations between the members of this group. It throws light on the reciprocal relation between incubation and immunity. The pathogenesis of the typhoid blood-picture must not be ascribed to the endotoxins *per se.* but to the lymphoid tissue reactions which they call forth. Any chronic tissue lymphocytosis may produce a similar blood-picture, for instance, the first stage of tuberculosis and splenic anemia. The generalized endothelial and lymphoid cell hyperplasia described by Mallory,[29] Edsall,

Longcope[30] and others and observed by Virchow, depends on the manner of intoxication, rather than on the nature of the intoxicant. Indeed, the colon bacillus produces a disease not only clinically identical with typhoid fever, as Coleman and Hastings report,[31] but also with the blood-picture as that observed in Eberthian infection.

The material for the present report consists of cases of typhoid and paratyphoid fever in my private practice and from the Englewood Hospital. The patient's leukocytes were examined every two or three days during the course of the disease. In this way I was able to secure from two to ten and twelve total and differential leukocyte counts for each day, with the exception of the first two days. This is, of course, quite excusable in view of the usually insidious and indefinite onset of typhoid fevers. From the literature I could gather only total white blood-counts, differential analyses being so rarely and poorly made that I had to abandon their use in this report. As many blood examinations were made as the patients and circumstances would allow. Arneth's method of establishing by nucleo-analysis a polynuclear blood-picture was not used, although most of the writers in this country follow this investigator. I consider it very important to examine *in toto* the white blood-life of the patient, by estimating the hemoglobin, securing the total leukocyte number, and dividing the white cells into four classes, the polymorphonuclear, the small mononuclears, the large mononuclears with the transitionals, and the eosinophils. The basophils were omitted as of little value. Care was taken not to make the blood-specimen right after a cold bath or cold sponge as Winternitz and Thayer cautioned.[32] The following nomenclature was thought more accurate, more simple and descriptive than either Arneth's[33] or Sondern's. For the total number the terms "normocytosis," "hypercytosis" and "hypocytosis" were used. In the differential counting I arranged the white cells into the polynuclear, mononuclear, mixed or di-cytosis, according to the percentages of either the polynuclears or mononuclears, or of both, being above or below the normal proportions. The reasons for this I have explained elsewhere.[34] The normal blood-picture being a dinormocytosis, I was able to establish the leukocytic alterations during the entire course of typhoid and paratyphoid fever. The physiognomy of this continual blood-picture may be summed up as follows:

Polynuclear hypercytosis (several hours, probably).
Polynuclear normocytosis (probably lasts only a day).
Polynuclear hypocytosis (up to 10-15th day).

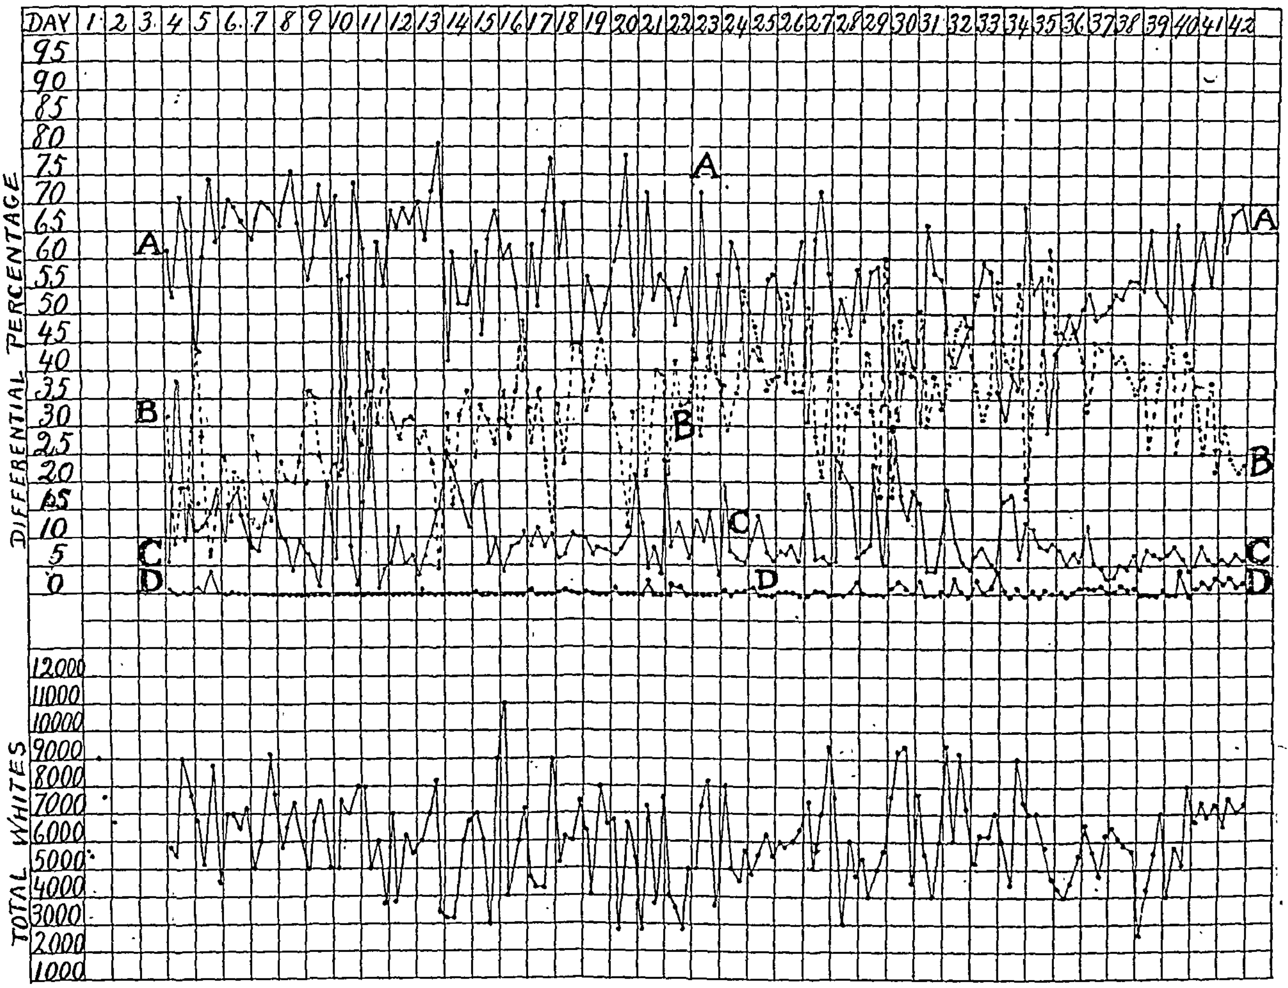

Chart 1.—The leukocytology of ortho-typhoid fevers. Four counts from each day for six weeks, obtained from thirty-six patients in private practice. A indicates polynuclears; B, small mononuclears; C, large mononuclears; D, eosinophils.

Di-normo-hypocytosis (10-15-18th day).
Mononuclear hypocytosis (15-25th day).
Mononuclear normocytosis (20-30th day).
Mononuclear hypercytosis (25-35th day).
Mixed or di-hypercytosis (30th-45th day).
Di-normocytosis (40-50th day).

Charts 2 and 3 are arranged schematically. Chart 1 illustrates the comparative constancy of a typhoidal blood-picture, persisting in spite of the well-timed shifting of its ingredient leukocyte-curves. The blood-picture of typhoid and paratyphoid is typical during the entire course of the disease. Its differential diagnostic value is as *great in the fourth week as in the first week.* It goes without saying that these total and differential leukocyte-curves represent the movements of the leukopoietic tissues (lymphoid cells, spleen and bone-marrow). As such their great prognostic value becomes self-evident.

A few preliminary remarks on the leukocytology of these kindred affections:

It is, of course, natural to accept the fact that in short duration, abortive or walking typhoid (see Chart 3) or paratyphoid fevers the leukocyte picture shows curves which are much shorter, though otherwise identical with those seen in true typhoid fever. It is also easily conceivable that the cytology of these infections in children would be tinged with the attributes of youth—resiliency, if not exuberance. Hence the shorter course and the greater intensity of blood-life, more lymphocytosis, relative and absolute, a lesser and shorter leukopenia and more marked mixed hypercytosis. Youth, health and the intensity of the existing affections must be considered in the framing of the typhoid-paratyphoid blood-picture. In judging the diagnosis or the prognosis, it is essential to base our opinion on the conjoint clinical and hematologic examinations.

THE INTERPRETATION OF THE TYPHOID-PARATYPHOID BLOOD-PICTURES

After a slight (supposed) initial rise, the total leukocytes drop rapidly and maintain a fairly constant low level until the fifth and sixth week of the disease, when, in juvenile patients or in patients with resilient blood-forming system, they return toward normocytosis, which yield to a more or less transitory mixed leukocytosis and then gradually shifts to a permanent normal level. As to whether these total white-cell changes are due to negative chemiotaxis according to Ehrlich, or due to a typhoid-endotoxin inhibition of the bone-marrow as O. Naegeli believes,[35] cannot as yet be definitely decided on. That the leukocytes are screened in the lung capillaries, as Bruce, Jacob Goldscheider and Andrewes maintain, is a hypothesis to which I cannot adhere. The leukopenia of typhoid affections looks to me like the prolonged ebb of the functional wave of cell immunity, a form of an hematopoiesis characterized by slow production and slow maturation of leukocytes. The polymorphonuclear cells after a probable initial rise diminish at first rapidly in number, then lose gradually but constantly until the end of the fourth week (see Charts 1, 2 and 3), when they return step by step toward the normal percentage. The polynuclear curve crosses the mononuclear wave twice, first on its downward course about the twenty-second or twenty-fourth day, and again on its ascent by the beginning of the seventh week. The small mononuclear leukocytes or lymphocyte curve is the exact counterpart of its predecessor polynuclear. Their movements are always complementary and compensatory. The lymphocytes rise after a slight initial drop, then move at a fairly even subnormal level until the fifteenth or eighteenth day, when they approach and cross their normal line, remain above normal for eight or ten days and then recede gradually into their normal proportions.

The large mononuclears and transitional cells form the most interesting part of the typhoid blood-picture. They are remarkably increased in number up to the end of the sixth week, then they regain their normal percentage. This myelemia, as Pappenheim calls it, was observed by Chetagurow in 1889. The resemblance of their curve to the polynuclear wave is, in my opinion, a very remote one, although Naegeli believes them to "follow the neutrophils mostly." There is no other prolonged leukopenia known to me in which there is such a continually high proportion of large mononuclears. This phenomenon I believe to be explainable in three ways: by a slow maturation of these cells into polynuclears, by their overproduction from the endothelial cells of the lymphoradicles, or by both conjointly.

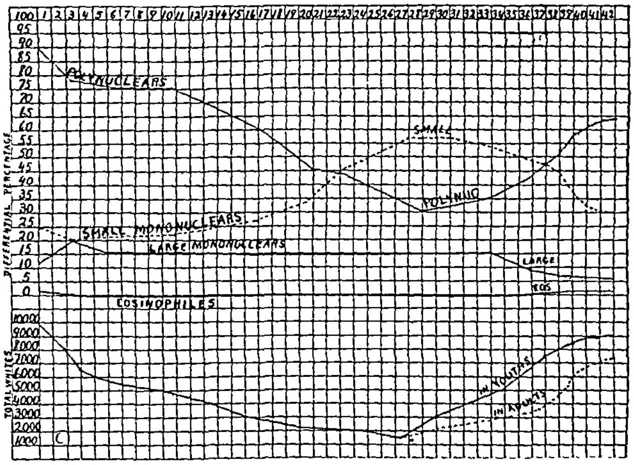

Chart 2.—"Leukocytology of orthotyphoid fever (schematic)."

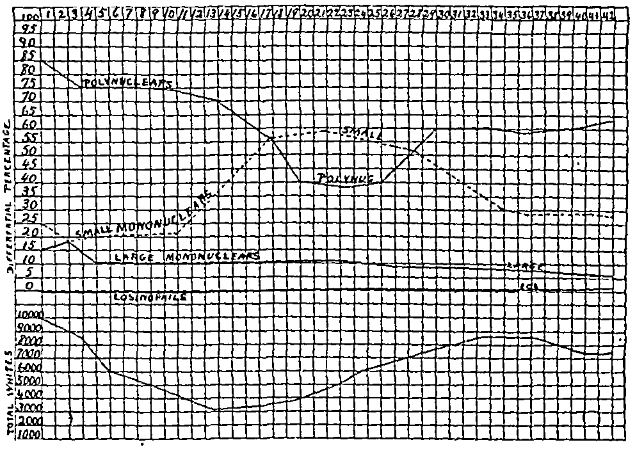

Chart 3.—"Leukocytology of paratyphoid fever (schematic)."

The eosinophils undoubtedly play an important rôle in typhoid fever cytology. I fully agree with Naegeli's dictum that "no febrile disease can be of typhoid nature if the eosinophils are present in normal or half-normal proportions." These cells disappear suddenly and totally, and return very cautiously around the begin- [illegible] sixth week.

---

[35] Naegeli, O.: Blutkrankheiten und Blutdiagnostik, 1908, p. 427.

CONCLUSIONS

1. There exists a typical typhoid and paratyphoid blood-picture throughout the course of these diseases.

2. This blood-picture is characteristic of the obligate parasites of the typhoid-colon group and constitutes, probably, the counterpart to that usually found in colon bacillus infections.

3. The leukocyte reactions of typhoid and paratyphoid infections must be interpreted as group-phenomena.

4. In the pathogenesis of this typhoid-paratyphoid blood-picture, the germs and lymphatic tissues play a joint rôle, but the character of the intoxication determines the blood-picture.

5. The diagnostic value of the leukocyte-picture is particularly great during the first ten days, while its prognostic value is especially marked in the last ten or fifteen days of the disease.

6. Repeated, combined total and differential leukocyte-counts must be made throughout the course of typhoid or paratyphoid fevers. The cytology of these affections can be appreciated in no other way.

7. The immunity with leukopenia of the typhoid-paratyphoid group and the immunity with active leukopoiesis of the colon wing of this family are evidently the two extreme phases of one fundamental process.

8. Blood-charts and reasoning by analogy show that the conception of the typhoid blood-picture as a group phenomenon within the typhoid-colon family is correct.

9. Each member of the typhoid-colon bacillus group is able to produce either a toxic gastro-enteritis or a true typhoid affection.

10. The close or fundamental kinship between the numerous members of the typhoid-colon group of bacilli is proved, first, clinically by the time-honored name of typhoid fevers, second, pathologically by their common faculty of producing ulcers in the gastro-intestinal tract, third, cytologically by their blood-picture, fourth, serologically by the coagglutination of Pfaundler, fifth, epidemiologically by Hazen's theorum of the Mills-Reinke phenomenon of typhoid and general mortality.

11. The law of periodicity of inorganic chemical elements, enounced by D. I. Mendeleeff in 1869, is in my opinion applicable to the distinct group-arrangement of organic, living microorganisms.

REMEDIES FOR ANIMAL PARASITES

A STUDY OF THE RELATIVE EFFICIENCY AND DANGER OF THYMOL AS COMPARED WITH CERTAIN OTHER REMEDIES PROPOSED FOR HOOKWORM DISEASE *

W. H. SCHULTZ, Ph.D.
WASHINGTON, D. C.

Thus far I have experimented with about twenty different remedies for ankylostoma aside from the action of various chemicals on the eggs and larvæ. It is desired to consider more in detail four of these remedies which at present seem to me to be of particular interest in treating hookworm disease, to call attention to some of the dangers accompanying the use of each and to suggest what laboratory experiment and clinical experience have shown to be the best method of expelling hookworm by these particular remedies. What I shall have to say, then, is of the nature of an experimental criticism interpreted in the light of many experiments on dogs, especially, infected and studied under conditions that admitted of proper control.[1]

THYMOL

One of the first substances to be used with any degree of success is thymol, which is one of the higher phenols known as isopropylmetakresol. It is difficultly soluble in water, 1 gm. in 1,100 c.c., but is very easily dissolved in alcohol, and less so in castor oil, olive oil and fats, than in alcohol. When the dry powder is taken after a twelve-hour fast, with the alimentary tract cleaned out by a saline or calomel purge, but little thymol is absorbed, most of it leaving the intestine by way of the feces. After 3 gm. doses daily for a long period of time, Blum was able to recover from human urine sufficient thymol compounds to analyze. These appear in the urine as thymolsulphuric acid, thymolglycuronic acid, thymolhydrochinonsulphuric acid, and a thymol chromogen. During twenty-four hours after taking 3 gm. of thymol one man eliminated thymolglycuronic acid equivalent to 0.2025 gm. dichlorthymolglycuronic acid.

When absorbed in sufficient quantities it causes marked depression, nausea, vomiting, severe headache, roaring in the ears, weak heart-beat, resulting in a thready pulse, muscle weakness, lowering of the body temperature, dizziness, and general collapse. In my experiments on dogs, the myocardiograms show the heart muscle largely responsible for most of the graver symptoms, its contractions grow more and more weak, resulting in a gradually lowered blood-pressure, until finally, if the amount of thymol in the blood is sufficient, the animal dies from low blood-pressure, due to diminished ventricular output. *Thymol also acts on the* mucous membrane, stimulating secretion of mucin and causing burning sensations and sometimes vomiting, in which case the patient may suffer intensely from its irritant action on the membranes of the mouth, nose, and throat. Should the drug be accidentally drawn into the lungs it may cause grave complications, even consolidation of that part of the lung tissue with which it comes in contact. In general, then, it may be said that thymol resembles phenol (carbolic acid) in action, but is less easily absorbed and is about one-fourth as toxic.

Bozzolo, in 1881, had occasion to treat ankylostomiasis, and discovered that thymol was efficient in expelling the parasite. At first he gave 2 to 10 gm. of the powder a day, followed by a weak alcoholic beverage, so as to have a weak solution of the drug in the alimentary tract. Later he gave 2 gm. every two hours until 12 gm. were given. *In the hands of later workers this treatment* proved effective, but too drastic, and after a number of mishaps smaller doses were recommended, the use of all thymol solvents forbidden, and more emphasis placed on vigorous purgatives to expel the parasites and diminish the possibility of further absorption of the drug after its function as a vermifuge had been fulfilled.

With thymol treatment, as with most treatments for intestinal parasites, too much emphasis cannot be placed on the proper preparation of the alimentary tract and the parasite before administering the antihelminthic. Since thymol combines with proteins and other substances taken as food, and by dilution alone is kept away from the parasites, the alimentary tract should be as empty as possible. To this end only sufficient food is eaten at noon on the day before taking thymol to insure against faintness. The evening meal ought to consist of beef broth; or some form of gruel. At about 8 or 9 p. m. a compound cathartic pill is taken. The following day the treatment proper begins, the best of which seems to be that so clearly outlined by Stiles,[2] in substance being that recommended by the Porto Rican Commission which has reported thousands of successful treatments. It is as follows:

---

* Read in the Section on Pharmacology and Therapeutics of the American Medical Association, at the Sixty-Second Annual Session, held at Los Angeles, June, 1911.

* From the Hygienic Laboratory of the U. S. Public Health and Marine-Hospital Service.

[1] The details of the experiments, along with a discussion of the other remedies studied, will appear in a bulletin from the Hygienic Laboratory in the near future.

> At 6 o'clock in the morning, one-half of the dose of thymol is taken in flat, 5-grain capsules, the finely powdered thymol being thoroughly mixed with one-half to one-third its bulk of milk-sugar to insure rapid disintegration of the mass in the stomach and intestine. The patient should lie down until some time after the drug has passed into the intestine; at 7:30 or 8 a. m. the second half of the calculated dose is taken and at 10 a. m. a vigorous purge, either of magnesium sulphate or of compound cathartic pill, is taken. The feces from now until the day following ought to be collected, washed and examined for parasites, and a week later a fresh sample examined for eggs to make sure of the efficiency of the method.

The dose of thymol should depend on the age and condition of the patient. Since absorption is much more rapid in young animals than in adults, and their protoplasm reacts more vigorously, the dose must be reduced. The body cells of badly infected individuals are also less able to withstand the toxic action of the drug, the numerous wounds in the intestinal mucosa favoring increased absorption of thymol, just as in the case of abraded surfaces in contact with phenol. Experiments on animals and clinical experience teach that the dose of thymol for both young animals and those weakened by disease must be only one-tenth to one-fifth that of a vigorous adult. The following doses represent the maximum amount of thymol recommended by the Porto Rican Commission and by Stiles to be given during one day for the age groups, respectively, to be given in two doses and modified, not to the age, but to the apparent maturity and vigor of the patient:

Age, Years.	Grains.		Grams.
Under 5	7½		0.5
From 5 to 9	15		1.0
From 10 to 14	30	or	2.0
From 15 to 19	45		3.0
From 20 to 59	60		4.0
Above 60	30–45		2.0 to 3.0

Treatment with submaximal doses of thymol expels only a fraction of the parasites and renders the residue in some way less susceptible to subsequent doses. Though only a part of the parasites are expelled, the patient at once reacts to the improved conditions of nutrition, the hemoglobin content is increased, the heart strengthened, and in general the bodily health is improved. For this reason instead of following within a few days the first treatment with a second, it seems best to wait and take advantage of the host's increased resistance to the drug because of the increased bodily vigor. Then if tolerance is developed by the parasite, use may be made of one of the other vermifuges discussed later.

Although thymol is generally conceded to be one of the most active hookworm expellants, it has certain drawbacks, chief of which are its irritant action, its toxicity when absorbed, and its tendency to cause tolerance in the parasite in excess of that which it develops for the host. These objections have encouraged the trial of other phenol compounds, but with little success, since those that are less soluble are likewise less active vermicides. Beta-naphthol, however, has been tried and with considerable success.

BETA-NAPHTHOL

Beta-naphthol is a naphthalin derivative, soluble at 25° C. in 950 parts of water and 0.61 parts of alcohol, is quite soluble in olive oil, castor oil, fats, and difficultly soluble in the saliva and in the acid gastric juice. Part of the beta-naphthol is absorbed in the intestine; just how much seems never to have been determined, but that which is absorbed is, according to Edlefsen, excreted by the kidneys as beta-naphthol gluconic acid, beta-naphthochinon, and possibly in other slightly modified forms. One of its chief dangers is that the kidney cells are apt to be affected, resulting in nephritis and subsequent albuminuria. The mucous membranes are affected by it, but there is not that intense burning of the mouth, throat, and stomach, following contact with the dry powder, which is experienced with thymol; on the contrary there is more of a numbing sensation of the tongue. Thus far I have found in the literature no cases of severe poisoning from its internal administration. Most of the cases of poisoning recorded are of patients treated for skin disease, this drug being, like phenol, readily absorbed by the skin when applied in ointments.

Colbert, after trying thymol in a few hundred cases of ankylostomiasis with a number of unpleasant results, employed beta-naphthol. Out of 5,000 patients, 4,056 were cured. A large number, however, had to be treated four or five times before the feces no longer contained eggs. Beta-naphthol is a weaker vermicide than thymol, consequently slower to effect a cure. In spite of this, Colbert recommends it above thymol because of the absence of the more objectionable properties of the latter. Fort, of Georgia, reports 374 successful treatments and recommends it highly.

The experiments in this laboratory confirm the reports of clinicians. Dogs stand beta-naphthol much better than they do thymol. It does not cause vomiting except with large doses and in prolonged treatment. It does, however, frequently produce considerable irritation of the genitalia after urinating, but thus far none of the animals developed either immediate or remote symptoms of a grave character. Since the parasites likewise react less vigorously toward this drug, and in equal doses beta-naphthol seems to be less active than thymol, probably the difference in activity is in proportion to their relative toxicity for the host. If further experiments prove this to be true there is no advantage in substituting beta-naphthol for thymol: less thymol should be used at a time and the number of treatments increased. But should the ratio of relative efficiency and that of the relative toxicity of these two compounds be in favor of beta-naphthol, then it is the more desirable and safer remedy in cases of children, anemic, and aged patients. This point I hope to prove in the near future.

In general the procedure of treatment and the precautions to be taken are the same as those described for thymol. For a vigorous adult the procedure is as follows:

> The patient is placed on a liquid diet: at 3 p. m. a mild cathartic of calomel or salts is given. On the second day at 7 a. m. 1 to 2 gm. of beta-naphthol, mixed with about one-third its weight of milk-sugar, is given in a gelatin capsule: at 8 a. m. 1 to 2 gm. more are given: at 11 a. m. a vigorous cathartic of salts or compound cathartic pill: at 12 a glass of milk and bread may be eaten, and after that the regular diet (Clayton, Fort).

MALE FERN

In Europe there is perhaps no vermicide so widely used as the ether extract of male fern. In the more northern portions of Europe it seems relatively easy to obtain very active samples of the rhizome, but in this country a high quality of it is difficult to purchase on the open market. To insure an active extract the best quality of rhizome, showing the characteristic green fracture, is necessary.

---

[2] Stiles, C. W.: Bull. U. S. P. H. and M.-H. S., 1910, No. 30.

Its active principles readily deteriorate with age, not only when isolated as such, but also as the crude extract and even as the dried rhizome itself. The extract is a mixture of substances, amongst which the most important are filicic acid (Lach), aspidin, albuspidin (Boehm), aspidinol (Boehm), flavaspidinic acid (Boehm), aspidinin (Boehm). Poulsson, Boehm, and Straub think that aspidin, albaspidin, and aspidinin are powerful smooth-muscle poisons, and Straub has later shown that male fern is primarily a plasma poison, attacking both smooth and striated muscle without destroying nervous conduction. These properties make it, theoretically, a powerful and effective poison for ankylostoma, and if the amount absorbed by the host can be controlled it has most of the essentials of a good vermifuge.

With due precautions against solvents and against too long contact with the mucosa of the alimentary tract, the factor of absorption can in part be controlled, but even then there is usually enough of the drug absorbed to enable one to detect it in the tissues of various organs, and filicic acid along with some of its split products appears in the urine. With moderate doses mild poisoning is very common, and large doses are attended with considerable danger. When poisoning occurs the patient experiences severe abdominal cramps, catarrhal and diarrheal conditions of the intestine, headache, dizziness, shortness of breath, yellow vision, and sometimes amblyopia and even temporary blindness. In the severest cases the person becomes delirious, is attacked with severe muscle-cramps which may develop into tonic spasms, and even death may ensue. In the severe cases in which recovery takes place, permanent unilateral or bilateral blindness results. Sidler-Huguenin, 1898, compiled seventy-eight cases of poisoning and twelve deaths; Nieden compiled forty-seven cases of injury to sight from male fern; nineteen cases showed double-sided, and fifteen one-sided amblyopia. According to Kalayama and Okamoto, in 32.5 per cent. of the cases of male fern poisoning there were varying degrees of visual derangement. Like thymol, then, this remedy is not absolutely safe, for only 5 gm. has caused severe poisoning in man. Various attempts have been made to eliminate the poison that is injurious to the host, retaining the substance that has a selective action for the parasite, but thus far these so-called active principles have been found unreliable.

Male fern extract had long been known as a teniacide, but Perona and Perroncito about 1881 brought it into prominence as a substance highly toxic for ankylostoma. Since then its efficiency as a vermicide has been amply demonstrated.

Fickerman treated 534 patients, the first dose curing 83.9 per cent. Laplanche found that the first dose cured 75.9 per cent. of 1,648 patients. Nagel compiled the results of about 4,000 cases, his observations extending over several years of time; mild poisoning was common. Tenholt treated about 10,202 worm patients, 74 per cent. requiring but one dose. Birgmann treated 22,000 patients with ankylostomiasis and observed only four cases of permanent blindness.

In treating hookworm disease by male fern it is not only essential to have a fresh ether extract, but it is necessary to prepare the alimentary tract for its reception. The mucosa should be free from mucin and from fatty foods. All solvents of male fern such as alcohol, fats, and oils, must be avoided, just as with thymol. Then in order to avoid unnecessary absorption after the drug has fulfilled its function of poisoning the parasite, it should be expelled as quickly as possible. Compound cathartic pills or magnesium sulphate seem to be the best cathartics. Since ether extract of male fern has a very disagreeable taste, it ought to be put up in capsules. Glutinoid capsules have been recommended, but when taken in these, larger doses seem to be necessary. The following procedure used in part by Goldman seems to be a good one:

For a vigorous adult 8 to 16 gm. of ether extract of malefern is put up in 1 gm. gelatin capsules. First day: Evening meal of meat broth or light soup; compound cathartic pill later, say about 8 p. m. Second day: 7 a. m. 1 gm. malefern every ten minutes until 4 to 8 gm. have been taken. One-half hour is then allowed to elapse and if no undesirable symptoms develop the remaining 4 to 8 gm. are taken, 1 gm. every five minutes. One to two hours later a vigorous purge is taken (calomel or salts). The feces should be washed and the worms counted; three to ten days later the feces are again examined for eggs, and if necessary the treatment repeated.

EUCALYPTUS AND CHLOROFORM

Another mixture known as "Hermann's Mixture" is of considerable interest. It is composed of 3 gm. of chloroform, 2 gm. of oil of eucalyptus, and 40 gm. of castor oil. This is divided into two doses and given at hour intervals.

Thus far I have been unable to find any cases of acute poisoning from pure oil of eucalyptus mixed with castor oil. It is known to have a local action on the skin, but otherwise little is known of its pharmacologic action. Two and one-half c.c. of oil of eucalyptus globulus in 10 c.c. of castor oil, given in a gelatin capsule to a 5 or 6 kilo. dog, causes vomiting. Judging from the contents of the vomit, the mixture caused an abundant flow of mucin, slightly tinged with blood. The same animal can take, apparently with little inconvenience, the same amount of eucalyptus oil if given at hourly intervals in doses of 1 c.c. mixed with 5 c.c. of castor oil.

It cannot, however, be said of chloroform that it is a harmless drug when taken in doses as usually recommended for expelling intestinal worms. As is well known, chloroform alone is a powerful irritant to all parts of the alimentary tract. It acts locally on the mucosa, causing lesions therein, and stimulates both the stomach and the intestine to very active movements. Being absorbed from all parts of the alimentary canal, especially the upper portion, it reaches the liver by a rather direct route and may result in acute poisoning. A 10 kilo. dog may show no outward signs of intoxication after ingesting 3 c.c. of chloroform thoroughly mixed with 10 c.c. of castor oil. Hookworms may be expelled within two and a half hours after giving the mixture. If, however, a second dose be taken three to four hours afterward, a dog, before lively and playful, soon ceases to be so, food is refused, vomiting may set in, and some hours later the animal is seized with acute mania-like symptoms and eventually dies. The postmortem findings of such animals reveal profuse lesions in the liver, the lobules, and in many places groups of them, being distinctly outlined by their yellow color, the pericardium shows a peculiar mottled appearance, and there is hemorrhage in the lungs, diaphragm, stomach and intestines.

There can be no doubt about the chloroform being responsible for these pathologic conditions, and such results place one on his guard in using chloroform internally. Its invidious action on the internal organs may not result in symptoms gross enough to be observed until considerable time has elapsed, thus tempting one to administer a second dose, the summated action of which may bring things to a crisis at once. Acute mania is reported in the case of a boy after taking for hookworms the prescribed dose of "Hermann's Mixture." The dose was probably that supposed to be taken by an adult, and should have been modified according to the age and condition of the patient, a matter to be considered at all times. Even then patients seem to rebel against a second treatment, and Colbert, Key, and Law each speak of it as dangerous and less efficient than beta-naphthol. Thus far I have found the remedy more efficient for dogs than beta-naphthol, and an excellent substitute for thymol in very refractory cases.

It is not quite clear just what part oil of eucalyptus plays in expelling ankylostoma, but until further data are at hand I am inclined to think it is simply an irritant to the parasites, causing in them rapid vermiform movements, and making them loosen their hold and change their position, in which case a vigorous purge may sweep them alive out of the intestine. The chloroform not only does this, but also anesthetizes them sufficiently to render them incapable of again taking hold of the mucosa while being expelled by the purgative action of the ricinolic acid. When quickly expelled in this way the worms are not at first very active, but placed in saline solution they soon become very active and may live twenty-four hours.

That chloroform is the most important constituent of this formula can easily be demonstrated by taking two infected dogs A and B. A is treated with 15 c.c. of castor oil plus 3 c.c. of eucalyptus globulus, in 3 doses an hour apart. After a second treatment only thirteen live worms were obtained. B is treated with 15 c.c. of castor oil and 3 c.c. of chloroform in doses one hour apart. Inside of 3½ hours after the last dose, feces were obtained containing 133 hookworms, and a few hours later 150 more were expelled, all of which were very active after being in water ten minutes. A second treatment some days later secured twenty-five hookworms; subsequent examination of the feces showed it free from eggs, and later after using the animal for a blood-pressure experiment, careful examination of the stomach and intestines showed the animal to be free from hookworm. Dog A was then treated with 15 c.c. of castor oil and 3 c.c. of chloroform, in three doses an hour apart; hookworms were obtained, and after the second treatment the feces showed no hookworm eggs.

These experiments seem to represent in general the relative action of eucalyptus and of chloroform. With some dogs a larger number of worms may be obtained after eucalyptus, but in such cases there is considerable blood in the feces, whereas chloroform is quite uniform in its action and always expels the worms more efficiently. So that one is justified in concluding that the oil of eucalyptus globulus is probably superfluous and at best simply an aid to the chloroform during the stage of irritation in causing the worms to loosen their hold on the mucosa.

CONCLUSIONS

1. *Any practical vermifuge to be effective in expelling uncinaria or ankylostoma must be an irritant of sufficient intensity to cause the parasite to loosen its hold.*

2. It should paralyze the neuromuscular apparatus to hinder the parasite from making fresh attachment.

3. Its relative toxicity for the parasite must be either much greater than that for the host or be much more readily absorbed by the former than by the latter.

As has already been pointed out, each of the above remedies is absorbed more or less from the alimentary tract, and Tenholt has even gone so far as to assume that only such drugs as are absorbed can be active in expelling ankylostoma. Since their method of taking food is by way of the mouth they must of necessity be poisoned by ingesting the tissues of the host already impregnated with the toxic substance, and if the host does not absorb sufficient thymol, beta-naphthol, male fern, etc., they remain fixed to the intestinal mucosa and are not expelled by the purgative.

My present experimental data suggest that this is at best only a part of the truth. It happens that drugs like thymol when combined with iodin or the benzole radicle are much less active vermicides than thymol itself. It is also true that thymol iodid, being much less soluble than thymol, is absorbed to a less extent by the intestinal mucosa. *A priori* this would seem to support the idea of Tenholt that thymol iodid has no action on hookworms because none of the drug is absorbed by the host. But if the worms themselves be studied in contact with solutions each of thymol and thymol iodid it is possible to explain the reaction of the worms towards the two drugs on the basis of amount of drug in actual contact with the parasite and the effect of introducing the iodin atom into the molecule, and thus lowering its toxicity. While, therefore, the drug absorbed by the host and ingested by the parasite as a part of the cell and plasma may have a toxic action on the worms, it seems that such drugs as thymol, male fern, chloroform, and beta-naphthol, act[1] by direct contact *with the worms, causing rapid vermiform movements,* and if the irritation is sufficiently great the worms *finally attempt to escape. From now on until paralysis sets in not a little of the surrounding media is ingested, since the mouth parts of the parasite are kept in constant action.* At this stage the intestinal contents of the host ought to be expelled so as to get rid of the surplus drug and the poisoned or anesthetized worms. Judging from the action on the worms *in vitro,* two to three hours seem to be about the time when the cathartic should begin its work. Although in the case of chloroform and eucalyptus the cathartic in the form of castor oil works hand in hand with the chloroform.

In conclusion it may be said that at present thymol is one of the most toxic vermicides for ankylostoma thus far proposed. It is easy to obtain, keeps well, is cheap, and is easily administered; it kills the parasites instead of merely paralyzing them. When taken under the care of a physician who is careful to gauge the dose in accordance with the physical condition of the host, it seems to be the best all-around remedy thus far studied. While dangerous in large doses, it differs from beta-naphthol, male fern, and chloroform, in that the danger is at once apparent and can be controlled by heart stimulants and by methods that help maintain a good blood-pressure until the drug has killed the parasite and the cathartic has removed the excess of thymol. Whereas, with the other remedies just mentioned the danger signals are less obvious and usually it is only after irreparable damage is done that one is aware that his patient is in danger of any after-effects.

Beta-naphthol is probably the next pure *chemical substance that ought to be tried* more *extensively on* human hookworm subjects. Persons affected with kidney lesions ought not to take it, and when used the urine should be examined to determine whether it causes albuminuria. If the maximum dosage of 2 to 4 gm., divided in two parts and given an hour apart, does not cause renal disturbances in adults, beta-naphthol has much to recommend it as a hookworm remedy.

Male fern at present has not much promise in this country because of the lack of care in collecting the rhizome and in preparing an active ethereal extract. This, however, is a condition which doubtless would soon be remedied if once considerable demand existed for an active extract.

At present there is but little reliable data on how efficient "Hermann's Mixture" is for expelling human hookworms, or what percentage of cases might show after-effects. It seems unnecessary to add such an irritating oil as eucalyptus globulus, and if chloroform is used it ought to be given with plenty of oil. It is best to divide the maximum 3 c.c. dose, for a vigorous adult, into 3 parts, 1 c.c. of chloroform to 10 c.c. of castor oil, given at hour intervals. Should vomiting occur before the chloroform is taken, stop the treatment, and if necessary change to thymol or beta-naphthol. By thus regulating the dose of chloroform, I have had excellent results with dogs, it has proven rapid in its action and thus far not followed by any evil after-effects. Should the chloroform-castor oil mixture act as favorably in human beings as it has for me in dogs, it will prove a universal worm remedy of great importance.

Finally it may be said that the best of remedies are but weak instruments of defense in stamping out this degrading disease. The weapon of offense must after all be proper disposal of fecal matter so that infection is rendered impossible. And what can be more effective in accomplishing this than the cultivation of a healthy public sentiment which will insist on its communal rights in this matter, protect the innocent, and by proper police regulation quickly punish the offender? To this end it would seem that the most effective line of attack is that led by Stiles and others who are endeavoring to educate the masses as to the importance of proper sanitation.

MY EXPERIENCE WITH HOOKWORM INFECTION IN THE DEEP GOLD MINES OF CALIFORNIA *

E. E. ENDICOTT, M.D.
County Physician and County Health Officer of Amador County
JACKSON, CAL.

The physician practicing medicine in the interior of the North American continent may have meager opportunity for the application of tropical medicine or meet few diseases foreign to the locality, but as new diseases, new industries, and a changing population take effect, then he may anticipate new enemies on which to test his skill.

I offer this paper without any anticipation of presenting anything new, but with the hope that my experience with uncinariasis, or hookworm infection, together with the few suggestions that I can make, in relation to its cure and particularly its prevention, may prove of value to the fraternity. I think that I can positively state, without fear of contradiction, that many individuals have gone down to an untimely end from hookworm infection, and we have helped to bury our mistakes by signing a death certificate for "miners' consumption" or some other disease, diagnosed symptomatically; while in many other cases, hookworm has been a contributing cause of death and has gone unrecognized, unheralded and unappreciated.

I may be radical when I say that I doubt if there are any deep mines in the United States, which have been in continual operation for a number of years, and which employ foreign laborers—miners who have worked in the mines of Cornwall, Austria, Italy or South Africa; and perhaps many other places before coming to this country—that are not more or less infected. In the mines along what is called the "mother lode," the deep gold-mining district of California, laborers of this class are employed.

These foreigners, without exception, come to the Pacific Coast from eastern ports, mostly from New York. They frequently stop *en route* at eastern mines, in Pennsylvania, Michigan and other places, and there is *no reason to believe that they do not infect these mines.*

These miners become infected by working from childhood in infected mines in the old country, and all are carriers, in the same sense as the typhoid carriers that we occasionally see. It is not only my opinion, but also that of Dr. Gunn, of San Francisco, whom I consider an authority on hookworm, that most mines in operation for a considerable length of time, employing this class of labor, where the conditions are favorable to their development, are infected with hookworm.

It might be well to quote at this time from Frohlich, Raillet, Stiles and others, that there are two distinct species of hookworm, the European and American, but I wish to say that if the European are not American, they should be, for they have been in this country long enough to be naturalized. These authorities state that the effects of the two species are not distinguishable and the treatment is the same.

Hookworm infection, if suspected, is not difficult to diagnose, but by the neophyte it may be overlooked. One may stand on the streets of any mining town along the "mother lode," when the miners come from and go to work, and with little chance of mistake point out the men infected with hookworm. Their skin has an appearance as peculiar to their trouble and as characteristic as is the cachexia of cancer.

When a patient complains of symptoms referable to gastro-enteritis, appendicitis, functional heart trouble, etc., the stools should be examined for the ova of hookworm. After an ordinary laxative the worms themselves are not found in the stool, only the eggs. Having once seen the ova, which are clearly pictured by recent books on the subject, there is little chance for mistake. Many cases of apparent heart trouble, gastro-enteritis, appendicitis, anemia, malaria, etc., yield like magic to hookworm treatment. I recall one case in which a miner, supposed to be dying of "miners' consumption," who was too weak to cross the street, was found to be infected with hookworm and responded nicely to the treatment; he is now back at work in the mine, doing hard manual labor, and is well and hearty.

It is not necessary to give a laxative to secure a sample of the stool. The patient can pick up a small amount of an ordinary stool on a toothpick and place it in a clean vial. A thin film of this spread on a slide, and examined under a 1/8 inch objective, without cover glass, will disclose the ova if they are present.

Eosinophilia is diagnostic evidence of hookworm infection; however, we must keep in mind the fact that eosinophilia is found in many other conditions which may simulate hookworm, viz., bronchial asthma, emphysema, phthisis with cavities, diseases of the nervous system. chlorosis, some diseases of the skin, and lithemia. The absolute diagnosis of uncinariasis consists in finding the ova under the microscope and later the worms after having administered the proper medicament.

---

* Read in the Section on Pharmacology and Therapeutics of the American Medical Association, at the Sixty-Second Annual Session, held at Los Angeles, June, 1911.

Treatment is simple and effective; the usual prescription consists of thymol in 5-grain doses every two hours until four doses are taken, to be preceded and followed by a saline laxative, a light supper, and no breakfast, before taking thymol; fats and alcoholic drinks are interdicted.

The other treatment most in use is the following:

℞	Gm. or c.c.		
Spiritus chloroformi	2|50		m xl
Olei eucalypti..................	1|25	or	m xx
Olei ricini...................q.s.	60|		℥ii

Sig.: Take one-half and repeat in one hour.

This latter treatment has an advantage in that it does not require the same precautions in diet and beverage, but I do not believe it to be so effective; besides it has its untoward effects, fainting, nausea. Some patients take the mixture with pleasure, while others become cyanosed and have to be placed in a recumbent position and given heart stimulants, due no doubt to the weakened condition and the effects of the chloroform.

Either method of treatment must be repeated at intervals of from three days to a week until all ova disappear from the feces. Any method of treatment should be followed by a good tonic, usually some iron preparation.

Now comes the most important part, that of prophylaxis: Having once cured the patient, how can we prevent reinfection? One can readily appreciate the folly of returning the cured person again to the same opportunity for reinfection without giving instruction and building barriers against such reinfection. Beyond question, the soil of these mines is infected. This fact has been absolutely proved by Dr. Gunn. The ova and larvæ may be seen in specimens of soil taken from the mines, and the mode of human infection is by skin contact with infected soil. Here I wish to say that the ground-itch, so common in the southern states and indicative of hookworm infection, is noticeable by its absence in the deep mines, although we do see an exceptional case.

The natural question that would arise in the mind of the novice, or those not acquainted with the extent of deep mines would be: Why not disinfect these mines? When it is remembered that one mine alone, near Jackson, is 3,600 feet deep (the deepest perpendicular shaft of any gold mine in the world), that its drifts, stopes, crosscuts, and raises cover acres, one can readily see the futility of such an attempt without a great disruption of the social and economic conditions of the locality. The question resolves itself into one of guarding the employees against reinfection and permitting the ova and larvæ in the infected soil to die a natural death.

In accord with this belief I would advise the placing of portable commodes at convenient places in the mines, these commodes to contain an antiseptic, and to be emptied at frequent intervals, and the miners to be instructed to use them exclusively instead of the sumps or drifts, as has been the habit, suspension or discharge from work to be the penalty for violation of this law. The custom of miners bathing only to the waist-line on returning from work must be abolished. A pool or cement tank should be provided and all underground employees be made to take a complete bath. I would also have provided at the changing-room at the mines as many disinfecting rooms as there are shifts, and that the miners be instructed to place their working clothes therein after returning from work, these clothes to be subjected to a thorough disinfecting by means of sulphur, formaldehyd or other disinfectants. All these mines are infested with hordes of rats, that are protected as scavengers, and it has occurred to me that the rodents may be a means of spreading the infection from one level to another. In line with this thought, I have secured rats from all the neighboring mines and have made careful examinations, but so far the results have been negative. At this time, however, I would not care to say that there is not a possibility that they might be carriers under certain circumstances; further investigation will be required.

In conclusion, I must say that to accomplish good results along the line of stamping out hookworm infection in the deep mines, regulations must be passed by state boards of health, empowering county and city health officers to see that the proper regulations are observed in the full sense of the word, otherwise Rockefeller's millions and our good efforts will be wasted on the desert air, and the hookworm will be left as a heritage and burden for those who follow.

HOOKWORM DISEASE IN CALIFORNIA, ITS IMPORTATION, DISSEMINATION AND PREVENTION *

HERBERT GUNN, M.D.
SAN FRANCISCO

Up to six years ago hookworm disease was unheard of in this state except for a few isolated imported cases. In 1905 I called attention to the fact that a large number of Porto Ricans were taking up residence in California and that over 50 per cent. of them were hookworm carriers.[1] During the following four or five years attention was frequently drawn to the subject, but no measures were instituted to control the importation of the disease until 1910, when Passed Assistant Surgeon Glover of the U. S. Public Health and Marine-Hospital Service, stationed at the Immigration Station at Angel Island, San Francisco, began the examination of immigrants for hookworm disease.

On account of the very efficient manner in which this work is being continued, it is safe to say that practically no hookworm carriers, coming under the jurisdiction of the immigration department, are now permitted to enter this port. So far as is known this is the only immigration station where such measures are taken, so that Chinese, Japanese, Hindus, Central Americans, etc., may readily enter United States territory without a question as to their being hookworm carriers.

In the latter part of 1910, under the auspices of the California State Board of Health, I investigated the conditions existing in certain gold mines in this state,[2] and found that the disease was endemic and the infection extensive, being as high as 75 per cent. in some of the mines.

[1] [illegible] d., April and August, 1905.

[2] Gunn, H.: Hookworm Disease in Mines of California, THE JOURNAL A. M. A., Jan. 28, 1911, p. 239.

During the last year or two several cases of hookworm disease, which unquestionably originated in the Hawaiian Islands, have been observed in San Francisco, which fact is not surprising as the plantations there must have been badly infected before now by the thousands of Porto Ricans who have been employed there for years, and by the Chinese and Japanese. Most of the Hawaiian plantation laborers, after a longer or shorter sojourn in the islands, come to the United States by way of San Francisco, where many remain temporarily, to go into the country districts throughout the state when labor is required, or to the fisheries in Alaska during the fishing season. At the present time there are thousands of these people in this state, or temporarily in the Alaska fisheries who will return in the fall of the year. In San Francisco there is a big colony of them always, but especially in the winter months when there is no employment in the country districts and when the Alaska fishermen have rejoined their families.

With the assistance of the Associated Charities of San Francisco, the San Francisco Board of Health, through a recently established Bureau of Tropical Medicine, of which I have charge, has been investigating the subject of the importation of hookworm disease and, in so far as the infection from the Hawaiian Islands is concerned, has reached definite conclusions. Of a total of 355 examinations of individuals coming to California from various tropical regions, 171 coming from Hawaii were examined especially with regard to hookworm infection, with the following result:

Natives of Spain, total examined.. ..	135	
Blood examination for eosinophilia. ..	135	
Eosin count 5 per cent. and higher....	68	or 50 per cent. plus
Stool examinations..............	60	
Ova of hookworm present....	9	
Percentage infected with hookworm...	15	

Twenty-six of the sixty, or over 40 per cent., were found to harbor parasites of some sort, among which may be mentioned *Ascaris lumbricoides, Oxyuris vermicularis, Trichocephalus dispar, Tænia nana,* and *Balantidium coli.*

Porto Ricans examined..............	36	
Blood examination for eosin.........	13	
Eosin count 5 per cent. and higher....	11	or 84 per cent. plus

These men were en route to Alaska and no stools could be obtained.

In the following no blood examinations have yet been made:

Porto Ricans, stool examinations.....	23
Hookworm ova present..............	13
Percentage infected with hookworm..	56 plus

Seventeen of the twenty-three, or over 73 per cent., showed parasites of some sort, among which were *Ascaris lumbricoides, Oxyuris vermicularis, Trichocephalus dispar,* one case of *Schistosomum mansonii* or lateral spined bilharzia, *Strongyloides intestinalis* and *Balantidium coli.*

In these examinations specimens were obtained from entire families, and in no case was special selection made on account of apparent sickness, so that the percentage of infection may be taken as a fair average. Many of those examined showed marked evidence of the disease, some being quite incapacitated for work and depending on the Associated Charities for their food-supplies. Many of the children were undeveloped, some in height and weight being 30 to 40 per cent. below the standard for their ages.

It is apparent that these unfortunate people, in addition to being a menace to the rural districts in which they reside, must be a source of considerable expense to the counties on account of sickness and its resultant poverty.

The results of the investigations at this time among the Porto Ricans correspond very closely with those I obtained six years ago when an examination of over 100 Porto Ricans in San Francisco showed an infection of more than 50 per cent.

At the present time the San Francisco Board of Health is investigating the subject in regard to other nationalities, but though cases have been encountered, a sufficient number of examinations on which to base conclusions has not yet been made.

Prevention of hookworm disease in California is a task of considerable magnitude, and can be accomplished only by the State Board of Health with the cooperation of the federal health authorities. On account of our geographic situation and our intimate intercourse with many tropical countries, it will be necessary to have permanently the facilities necessary to combat the disease.

It will be necessary in the first place to prevent, so far as possible, the further importation of the disease, and in the second place to eradicate the disease now existing in the state.

To prevent further cases entering will necessitate the examination of certain classes known to be more or less infected (e. g., the laborers arriving at present from the Hawaiian Islands and a large proportion of the laborers now in the Alaska fisheries when they return), and the compulsory treatment of all found infected. There should be compulsory treatment of such persons as are found infected at the immigration station, who for legal reasons cannot be detained there for treatment.

It would probably be necessary to have hospital facilities such as the federal government maintains at the Immigration Station on Angel Island, where work somewhat similar to that outlined above is carried out.

In dealing with the disease as already existing in this state, the work of greatest importance would be in the mines, and here the requirements are very clearly indicated:

1. An examination should be made of every mine in the state in order to determine the extent of the infection.
2. Mine officials should be educated as to the importance of hookworm disease and mine sanitation.
3. Regulations should be promulgated and enforced regarding the examination of employees, the treatment of infected persons and mine sanitation.

The necessity of state regulation is clearly demonstrated by the fact that practically no attention has been given the subject by mine officials since the investigations of the State Board of Health eight months ago brought it to their notice.

In only one mine has any attempt been made systematically to examine the men and treat those found infected, and here only twenty-nine have been examined, showing over 75 per cent. positive.

It is quite impossible for the manager of one mine to carry out preventive measures, no matter how anxious he may be to do so, when adjoining mines are doing nothing, because the miners, many of them very ignorant, become suspicious and avoid the mine in which the requirements are so strict and unusual.

The management of individuals outside of mines and scattered about the state presents many difficulties, but the situation can best be controlled by proper sanitary measures. In some parts of the state, however, there are aggregations of certain people known to be more or less heavily infected, e. g., Hindus, Chinese, Japanese, Mexicans, etc., and these should be especially considered.

To summarize:

1. Hookworm disease has been extensively imported into California in the past.
2. It is still being largely imported at the present time.
3. The deep gold-mines of the state are as badly infected as many of the European mines.
4. In all probability some of the rural districts, if examined, could be demonstrated to be infected.
5. The only preventive measures employed are being taken by the federal authorities, and these are totally inadequate, as they are in operation in only one immigration station, and further, do not cover a large class of people who bring in the infection.

240 Stockton Street.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. SCHULTZ, ENDICOTT AND GUNN

DR. THEODORE G. DAVIS, Los Angeles, Cal.: I should like to ask Dr. Gunn whether he makes counts of the red blood-cells? The reason I ask the question is that very recently a cattleman, who has lived out of doors all his life overseeing a cattle ranch in San Obispo County, California, came to me for treatment. He had weighed 180 pounds; when he came to me he weighed 120. He had gradually become so debilitated that he was not able to pursue his work, which was to oversee his ranch. I found that he had hookworm and while I made no count of the red blood-cells there was a marked degeneration of the stroma of the cells and the hemoglobin gradually dropped after I first saw him from 80 per cent. down to 65 per cent. But the point that I wish to bring out is a practical point in the estimation or rather the recovery of the hematoidin from the urine of these patients, and also the effect on the liver of this disease, and recovery of the bile acids from the urine. It is, so far as I know, original. I have been working on it for more than three years. This may be applied to cancer and other diseases that produce substances causing degeneration of the red cell. Three ounces of the urine are acidified with hydrochloric acid and heated slowly over a low flame until bubbles begin to rise, or practically to the boiling point. It is then set aside to cool and is covered with ether.

It should not be shaken, but twisted upside down a few times. The hematoidin will be recovered from the urine in the form of hematin and the bile acids. By removing the ether carefully with a pipette, on a porcelain dish the hematin will be deposited on the upper portion and the bile acids will be on the bottom of the dish, very plain and yellow. If a dilute solution of sodium hydroxid is added to the bile acids and a little water the biliary compounds are washed out and the hematin left on the dish. If one wishes to test the substance further for bile I would suggest to try Torquay's test. Torquay's test consists of 1 part of methyl violet in 1,000 of water. If one takes two test-tubes equally filled with Torquay's test and drops in one tube a few drops of the solution of the bile acids or salt it will cause a disappearance of the blue tint of the methyl violet solution, only the red remaining. I have used this method for over three years in the various disease conditions causing destruction of hemoglobin or the red cells—in leukemia, both lymphatic and splenic, cancer of rectum and stomach, in hookworm disease and the various cardiac and intestinal diseases affecting the liver. In cases of babesia from Yuma, Arizona and Mexico, as well as estivo-malarial fever and other infections, I have found this test very suggestive as well as confirmatory.

DR. JOHN W. COLBERT, Albuquerque, N. M.: It has been my privilege to make an extensive investigation of hookworm conditions in Arizona, New Mexico, Mexico and Porto Rico during the past eight years. In the past eight years I have treated over 10,000 patients, having administered more than 50,000 treatments, and my conclusion is this: Thymol is the most powerful antihelminthic, and is the best remedy in the treatment of hospital cases. Its depressant effect is too great, however, to permit the drug to be entrusted in the hands of clinic or home patients. For these patients beta-naphtol should be given. True, it is not so powerful as the thymol, but its depressant effect is not nearly so marked. There is practically no danger in using the beta-naphtol. About seven years ago I tried the eucalyptus oil and castor oil, as suggested by Dr. Phillips, on ten hospital patients, and all suffered marked dizziness, considerable gastric irritation, and in a few cases considerable collapse, and all refused the second dose. I was therefore unable to follow up the treatment. Of the ten patients there was an average of 424 worms passed from the one dose. With beta-naphtol and thymol my average in 5,000 patients in Porto Rico was a little over 1,000 expelled from one dose.

Dr. Gunn only touched on a very important source of importation here in California, and also in Arizona and New Mexico. I refer to the Mexicans working along our railroads—our track laborers. Last August I presented this subject before the Pacific Coast Railway Surgeons' Association in San Francisco. At that time I reported eighteen cases which had come under my observation in two years' time. Within the past year I have seen almost fifty cases among these track laborers, showing that the condition is on the increase. I am fortunately situated in being near the distribution point for these Mexicans, and have examined many of them before they were sent into Arizona and California, and I do not believe that I overestimate conditions in stating that between 15 and 20 per cent. of these men harbor the hookworm. These investigations were made before the Mexican revolution—the recent insurrection—and we must remember that during this insurrection many of these same laborers for many months had been living in open, insanitary camps and going barefooted, and to-day I believe that this percentage is considerably increased. A few days ago I saw a news item, under date of June 18, stating that railway communication had been resumed between El Paso, Texas, and Chihuahua, Mex., and that the first train entering El Paso had on board 1,100 Mexican laborers for contract work in California and Arizona, all of them coming from points south of the city of Chihuahua. From personal investigations I have found that twelve of the states south of Chihuahua have hookworm disease. I am sure that you will find this condition spreading very rapidly. I want to call your attention to the fact that the warm, rainy season is the time *par excellence* for the hatching of the uncinaria ovum.

I have brought this condition to the attention of the officials of the Santa Fe Railroad, and they have already introduced proper sanitary measures to prevent a spread of the infection. We promptly deport the patients as soon as the cases are diagnosed. Within the past two weeks bulletins have been sent to all officials of the track department giving instructions as to adequate sanitation among the men, compelling the digging of trench latrines along the line of work for the men to use during the hours of work. I think this is a matter to be brought to the attention of the officials of other railroads. I wish to state furthermore that I have brought this to the attention of the Public Health and Marine-Hospital Service and this service has instructed all of their surgeons stationed along the Mexican border to be on the lookout for this disease, and they will cheerfully and readily aid any physician in deporting any one found with the disease.

DR. HARRY R. OLLIVER, San Francisco: It is interesting to know that hookworm is an ancient disease, quite accurate description of it being given in the Ebers Papyrus. In modern times it first occurred in Italy in the workers on the St. Gothard tunnel; then traveled down the Rhine to the mines of Westphalia; thence to Cornwall; then to America, etc. It is an interesting question as to the origin of the New World or American variety, whether indigenous to the United States or brought here by Africans. That the latter is probably true is emphasized by the finding of this variety in the interior of Africa. It is also traceable through the West Indies, Panama and the Philippine Islands. As pointed out by Dr. Gunn, laborers returning from the Hawaiian Islands are almost sure to bring it here, and the conditions here are most suitable for its propagation. It is especially true of the middle and southern parts of the state, where the irrigation projects are becoming so extensive and the soil, moisture and temperature are ideal for the propagation of the parasite. These laborers naturally take to agricultural pursuits, which predominate in these districts. This, in connection with already infected mines, gives rise to a decided danger of the infection of a large part of California. I believe that basing estimates on 50 per cent. of Porto Ricans being infected, we have in California, over 20,000 cases of hookworm disease.

DR. REID HUNT, Washington, D. C.: Do you get any encouraging results in disinfecting the excreta? I have done no work myself, but Dr. Stiles seems to have about given up in despair the possibility of finding anything that will destroy ova in excreta. Solutions of phenol (carbolic acid) for weeks had little effect. He found that if feces were collected in a septic tank most of the ova disappeared in two or three months.

DR. E. E. ENDICOTT, Jackson, Cal.: It has never been my experience to see a live worm. They were all dead when they got here. I do not know whether it has been thoroughly demonstrated as to how long the ova would live. They can stand a good deal of heat and a good deal of cold and possibly Dr. Gunn would be better informed on that line than myself.

DR. HERBERT GUNN, San Francisco: On account of the number of patients examined it was impossible to make relative counts. All that was done was a rapid count for eosinophilia, and that was apparent after thirty cells were counted. Ordinarily 100 cells were counted. Thymol I have used in large doses in a patient with marked nephritis of chronic character without any ill effect whatever. I have used the eucalyptus and chloroform mixture quite extensively and never had any ill effects from it. Thymol I have used in clinic work in San Francisco, depending on the patients to carry out directions as to preparation and after treatment. I had one patient who was pretty badly poisoned. I saw another case of poisoning in a hospital and only a moderate dose of thymol had been taken. I think, however, that it has been shown that thymol can be given without much danger when reasonable precautions are taken. At the present time in clinic work and when patients are not to be under observation during treatment. I use eucalyptus and chloroform exclusively. The nausea which frequently results when these drugs are given in castor oil may be avoided if they are administered in capsules. Fifteen minims of eucalyptol and 45 minims of chloroform are put into eight No. 1 capsules. These are sealed with a little water and enclosed in No. 0 capsules, also sealed, and then covered slightly with salol. These are administered at intervals for an hour. I have used this without producing the slightest trouble or irritation. The treatment is, of course, preceded and followed by a laxative. I think Dr. Endicott is perfectly right in regard to the mortality in the mines. I know when I was up there we saw many persons on the streets who presented evidence of grave anemia. In San Francisco I have had two deaths. One was in a Spanish woman who came from Honolulu and who had a hemoglobin of 30 or 40 and general anasarca. Another case I had was in a young Porto Rican boy who had also been in Honolulu and who died of inanition, having been sick a long time. I recently had referred to me in San Francisco a young student who had worked in the mines in Jackson for two months during a vacation. His temperature was 103 F., hemoglobin about 60. The peculiar muddy color was pronounced and he was very sick. He had been unable to keep up with his work at the university for months. The temperature in hookworm disease is quite frequently irregular. I have seen cases in which the temperature ran along so that it was suspected that the patients had malaria or typhoid. Frequently there is a slight fever. One of the cases I saw in the mines had been diagnosed as appendicitis; the symptoms disappeared immediately after treatment. A second case in which this diagnosis was made was seen in San Francisco. The point Dr. Colbert brings out regarding the Mexicans is very important. I had no idea that there were so many coming in and it shows that there should be some examination made on the Mexican border. Such inspection to be of any value would necessitate the routine examination of the stools or blood, as many of the hookworm carriers present no outward evidence of the disease. Regarding the life of the parasite, ova of the hookworm have remained alive for over a year in the laboratory, and the probabilities are that, under favorable conditions, they would live as long in the mines. As to the life of the parasite in the body, I have had cases in which it was alive for seven or eight years and I believe in estimating whether a case has originated here or outside one should give nine or ten years as being the limit of time. In regard to the material used for destroying the ova, it is claimed that common salt is one of the most efficient for preventing the growth of the ova in the soil.

BRAIN SURGERY *

CASSIUS C. ROGERS, A.M., M.D.
CHICAGO

I wish to consider briefly a series of thirty-five cases of unfavorable intracranial surgical lesions in which I have operated, comparing the results obtained in the cases of patients operated on early with the results obtained in the cases of those operated on late.

The results have not been flattering, but when we consider the duration and seriousness of the malady, the results are perhaps as satisfactory as those obtained in other surgical conditions that have been as long neglected and injudiciously treated.

Attempts are at once made to arrest hemorrhage, evacuate and drain abscesses, remove or drain cysts and remove tumors when located in accessible locations in all cavities except the cranial. Why should this be the exception when so often the hemorrhage, abscess, cyst or tumor can be so easily, correctly and accurately diagnosed and located, especially when it is located in focal areas, and frequently when no focal symptoms are present, the lesions being located in a silent area?

Time should be taken and careful and systematic examination should be made; under no consideration except in emergencies should the skull be opened until all means have been exhausted in the attempt to diagnose and locate the lesions. Skiagraphs of anterior, posterior and lateral views should be taken. The Wassermann and tuberculin tests should always be made as well as a complete blood test and uranalysis. And above all, if the patient is mentally impaired, he should be under close observation until all peculiarities are noted and their meaning fully interpreted. When at last operation is decided on, the site should be located and a large skin and osseous flap reflected, making possible the examination of a large area of the brain.

HEMORRHAGE

Hemorrhage due to trauma or to other causes may be classified under four heads: Intraventricular; intracerebral as in Case 4, Table 1, Series 1; subdural as in Case 8, Table 1, Series 1; supradural as in Case 11, Table 1, Series 1. It is the last two varieties that I wish to consider surgically.

In the subdural, the blood is at once distributed over a large area, being carried by the circulating cerebral spinal fluid. A general irritation is soon produced, perhaps at first it is mild, but later the patient may develop marked and diffuse muscular twitching and violent clonic and tonic movements with symptoms of intracranial pressure. The withdrawal of cerebro-

spinal fluid by lumbar puncture demonstrates the presence of blood. If the hemorrhage is severe, the symptoms are exaggerated, intracranial pressure is soon produced, and unconsciousness may be the result. In many of these cases the patients are relieved almost instantly and often permanently, by simply relieving intracranial pressure by decompression and by the opening of the dura.

Supradural hemorrhage is more localized and usually at the site of injury. If slight, there may be only local headache; if extensive there may be all the symptoms of intracranial pressure, headache, vomiting, vertigo, slow pulse, slow respirations and at last unconsciousness. In the former condition, if the symptoms are not relieved in a few days, the clot should be evacuated through a large opening in the skull; in the latter condition this should always be done:

First, to prevent infection of the clot, thus preventing the formation of an abscess, and second, to prevent organization and calcification of the clot, thus preventing irritation and adhesions which later produce epilepsy.

Intracranial pressure sufficient to cause headache, cerebral or projectile vomiting (vomiting without nausea, irrespective of the ingestion of food) and choked disk that is not improved in three weeks and relieved after six weeks of internal medication should be considered a surgical case and relieved by removing the cause, if located in a site amenable to surgery, or by subtemporal decompression (Cushing's method) if the lesion is in an unfavorable surgical location.

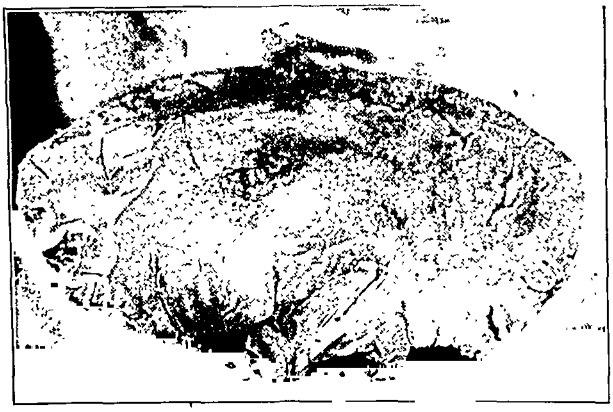

Fig. 1.—Hemorrhagic cysts within the brain.

Many conditions such as hemorrhage, edema, avascular gumma, etc., which stubbornly resisted such treatment before the intracranial pressure was relieved will readily yield to internal medicine after decompression.

Following injuries to the head, if the patient is rendered unconscious, regains consciousness in a short time and then again gradually becomes unconscious, and if the respirations are slow, deep and labored, the pulse slow, full and bounding, or weak, the temperature normal or subnormal, I make it a rule to advise operative interference at once, to relieve pressure produced by either hemorrhage or edema and thus to prevent complications and an unfavorable termination, using for the anesthesia, chloroform, and recently, gas (Crile method). Do not procrastinate in these cases; do as little as possible as quickly and thoroughly as possible, to assist the patient past the critical period; later perform a more thorough and complete operation if necessary.

ABSCESSES

Supradural abscesses originating from acute or chronic suppurative otitis media should be freely drained by removing a plate of skull just above the mastoid and drainage established. Draining through the roof of the mastoid will not give adequate drainage.

Subdural or intracerebral abscesses should be drained by removing a large plate of skull from over the region of the abscess. The dura should be freely opened, and if subdural, the abscess should be drained. If the abscess is intracerebral, the dura should be opened and evacuation of the abscess delayed until adhesions form between the dura and brain, thus preventing diffuse meningitis.

Subdural, supradural and intracerebral abscesses may persist for years and may date back to some slight injury produced many years before and long since forgotten; in some cases, the patients afflicted with them have spent many years in our state institutions for the insane for the want of a correct diagnosis and proper treatment.

CYSTS

Cysts result from many causes but frequently from irritation produced by small hemorrhages. They are frequently subarachnoid as described by Krause.[1] The fluid from the cyst will coagulate, while spinal fluid will not. Cysts may be the result of liquefied glioma.

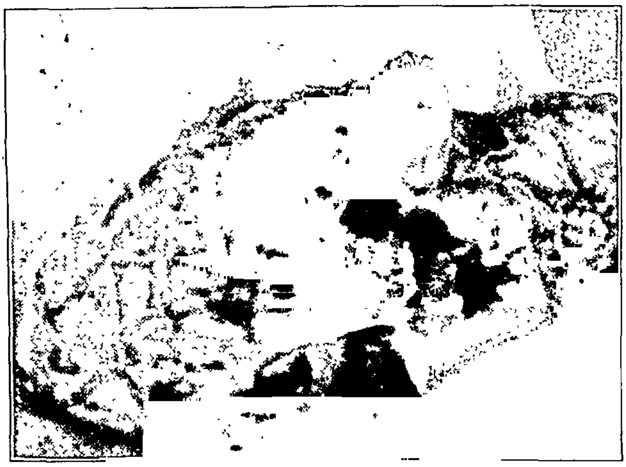

Fig. 2.—Large temporosphenoidal abscess. Series 1, Table 1, Case 8.

TUMORS

All varieties of tumors have been found in the brain, malignant and benign. Under all circumstances, the symptoms of headache, dizziness, vertigo, vomiting, impairment of vision, due to intracranial pressure can and should be relieved early by decompression. Constant, persistent, localized headache should demand our most earnest attention and all efforts made to determine the cause, as it is often in the location of the intracranial lesion and can be relieved by relieving tension.

SUMMARY

1. In cases of suspected tumor the patients should not be treated over long periods of time by antisyphilitic remedies.

2. A Wassermann test should always be made and if positive and the gumma is avascular, the tumor will not

yield to antisyphilitic treatment until pressure is relieved.[2]

3. The patient should have the benefit of early operative interference.

4. Intracranial hemorrhage should be evacuated in all cases in which the patient lives long enough to secure a skilled surgeon to relieve pressure, to prevent infection and abscess formation, and to prevent adhesions which will produce epilepsy in future years.

5. Intracranial pressure should be relieved by decompression to relieve and prevent constant and localized headaches, cerebral vomiting and impairment of vision.

6. Antisyphilitic remedies should not be given over long periods of time unless marked improvement is obtained within from three to six weeks.

7. Tuberculosis test should be made in all suspicious cases, in which the presence of tuberculosis is not positively known.

8. Epilepsy seldom develops before eighteen months after injury, and may develop many years later.

REPORTS OF CASES

SERIES 1 (Table 1).—CASE 4.—Mr. W., aged 51, American, clerk, four years previous to entering the Willard Hospital Jan. 6, 1909, had a stroke of paralysis involving the right side. This slowly improved until the patient was able to be up and around and at his work.

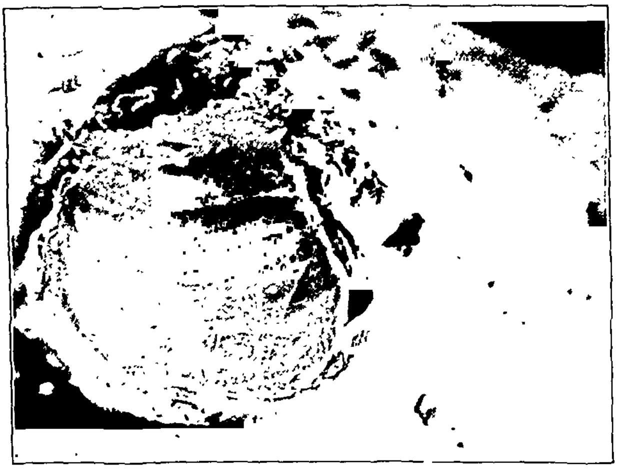

Fig. 3.—Chronic syphilitic meningitis. Series 2, Table 2, Case 4.

A year later he commenced to have temporal headaches on the left side, and for three years sought medical aid without relief. Jan. 7, 1909, I opened the skull in the left temporal region, found a large abscess in the temporal sphenoid lobe and drained it (Figure 1). Patient died on the fifth day from acute meningitis. Autopsy showed cysts of the brain and hemorrhagic areas.

SERIES 1 (Table 1).—CASE 8.—Mr. K., aged 59, German, contractor. Entered the Willard Hospital Dec. 12, 1910. Twenty-one days before entering the hospital while on his way to work he had been struck by a street car and rendered unconscious. He was taken to a hospital and treated. On the twenty-first day there was no sign of return of consciousness. He became very restless and noisy. His pulse was slow, his temperature was 102, and his respirations were slow and deep. He developed paralysis of the left side. He was transferred to the Willard Hospital, where I first saw him.

The diagnosis was fracture of the skull with intracranial hemorrhage. I advised operation. December 12 I opened the skull over the right motor area and found the large subdural hemorrhage (Fig. 2). The dura was opened and a large blood-clot as well as a large quantity of liquid blood was evacuated. The patient was returned to bed; he was conscious and recognized his family about twenty-four hours after the operation. He remained conscious for one week, when he again complained of severe headachs in the right mastoid and supramastoid region. Two days later I advised a second operation, as the patient again developed delirium. The radical mastoid was done, as well as removing a plate of skull over the mastoid region. An abscess was found in the temporosphenoidal lobe and was drained. The patient improved for a few days and then gradually grew worse.

We again opened and explored in the temporal region, draining another abscess. In all, we drained three abscesses in the forty-seven days that the patient was under our care. He died Jan. 27, 1911, forty-seven days after entering the hospital and two days after the last operation, from an abscess in the templar sphenoidal lobe. Autopsy was held by the coroner physician, Dr. Hunter, who gave the following report: "Patient came to his death from multiple abscesses of the brain, following an injury sixty-eight days previous to his death."

Summary.—Fracture of the vault and base of the skull; patient unconscious twenty-one days before operation; conscious twenty-four hours after operation; unconscious eight days after operation, and unconscious or semi-conscious until death.

SERIES 2 (Table 2).—CASE 4.—Mrs. D., aged 32, housewife, American, mother of four children—healthy, about one and one-half years before entering the Willard Hospital (April 13, 1909) complained of headache on the right side. Diagnosis, hysteria. Epilepsy followed. Headache became worse and worse, with cerebral vomiting, unconsciousness, and almost complete blindness. Patient entered Willard Hospital having been unconscious for about two weeks; left hemiplegia. Right motor area was operated on; dura mater was opened; brain bulged; tumor elicited but could not be removed; plate of bone was removed and skin sutured. Large tumor developed. Later skin separated and cerebral fungi formed. Patient gained consciousness; talked naturally and freely; could recognize her friends. She died May 29, forty-six days after the operation. At autopsy, gumma of brain was found with syphilitic meningitis (Fig. 3).

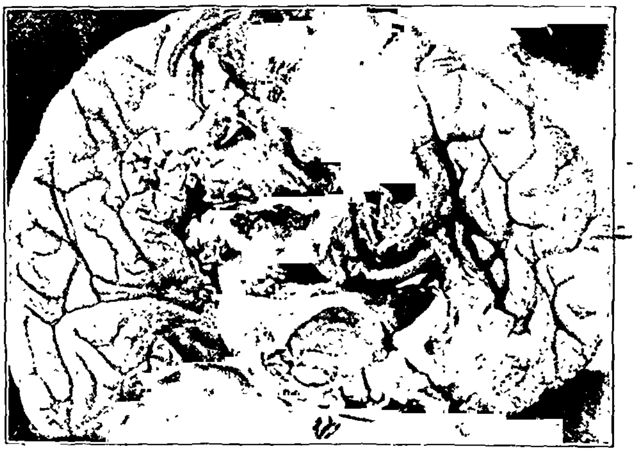

Fig. 4.—Multiple cysts of the brain, Table 2, Case 11.

SERIES 2 (Table 2).—CASE 11.—M. P., aged 8, entered hospital July 9, 1910; died July 19. March 1 patient came home from school feeling tired. A physician was called. There was some fever. The diagnosis was grip. Patient stayed home from school three weeks. Three weeks later had vomiting without nausea associated with headache, left parietal region, lasting twenty-four hours. Diagnosis was acute gastritis. Headache and vomiting continued at intervals until June 25, when the patient became unconscious, remaining so for twenty-four hours. Right hemiplegia was present on return of consciousness. July 9 patient entered Willard Hospital with right

8	B	F	65	Jew.	House wife	Fell on stairs	Parieto-occipital	Swollen	R. side	Unconscious	Opened skull and dura, L. motor area, large clot	8 days	F.W.	1-30, '11	Died	3 days	Cerebral hemorrhage
9	L	M	42	Jew.	Contractor	Scaffold fell	R. motor area	Lacerated	L. side	Unconscious	Opened skull, R. motor area	7 days	F.W.	4-11, '10	Died	6 hrs.	Cerebral hemorrhage
10	P	F	14	Polish	School-girl	Jumped from porch 14 feet	R. motor area	Negative	L. side	Epilepsy	R. motor area decompressed	2 years	F.W	10-5, '08	Epilepsy cured, greatly impr. paral.		
11	B	M	28	Am.	Laborer	Kicked by horse	R. front eminence	Lacerated	None	Epilepsy	Opened skull, R. front eminence	6 years	F.W.	3- , '06	Cured		
12	C	M	4	Am.	Child	Forceps delivery	R. motor area	Lacerated	L. side	Epilepsy	Opened skull, R. motor area	4 years	F.W.	3-15, '09	Epilepsy cured, paral. greatly improved		
13	W	M	21	Am.	Farmer	Kicked by horse	L. front	Lacerated	None	Epilepsy	Removed deformed fracture	15 years	F.W.	3- , '09	Died	1 week	Pneumonia

Number of cases, 13; number of deaths, 6; average time of unconsciousness before operation, 8 days. All patients who received surgical interference within 24 hours lived.

hemiplegia, vomiting at intervals, severe headache and Babinski constant both feet. Choked disk was marked. Diagnosis was marked intracranial pressure. I advised decompression to relieve pressure (refused). I sought expert opinions; all disagreed with me. July 10, patient was unconscious four hours; regained consciousness but complained of severe headache. July 11, headache was very severe. Patient improved from July 12 until on July 15, she went into complete coma. She was operated on July 15 under chloroform anesthesia. The child gained consciousness after large cyst was evacuated. Died double pneumonia July 19 (Fig. 4).

NOTE:—Complete histories of all cases are in my possession but are not submitted for publication on account of their length.

I am indebted to Dr. B. H. Orndorff for all laboratory work done.

7 Madison Street.

ANESTHESIA FROM NITROUS OXID-OXYGEN PLUS CARBON DIOXID

WITH SPECIAL REFERENCE TO COMBATING SHOCK *

E. G. MARTIN, M.D.
DETROIT

My purpose in presenting a paper on nitrous oxid-oxygen is to bring out, as forcefully and briefly as possible, its advantages and the added value of rebreathing to combat shock.

Some forty years ago, Dr. Andrews of Chicago discovered that by adding oxygen to nitrous oxid during its administration, the cyanosis was eliminated without impairment to its anesthetic properties. Since that time nitrous oxid has been widely used, but considered mostly as a dental anesthetic and for use in very minor surgical operations; the layman knows it as "laughing gas." During the last few years attention has been called to nitrous oxid anesthesia more seriously, and after extensive use and investigation by some of our leading surgeons—such as Crile, Meyer, Halsted, Kelley, Bevan, and the extended laboratory investigations of Hamburger and Ewing—of the comparative effects of nitrous oxid, ether, and chloroform narcosis on the blood, the American Medical Association reports through its commission on anesthesia that "as a routine anesthetic, nitrous oxid has a peculiar value, . . . and in the hands of highly skilled anesthetists, the method is the best yet devised."

Hamburger and Ewing say as to ether:

> The color index shows a rather constant drop, starting immediately after anesthesia and reaching its lowest point on the fifth and sixth days. This would indicate a relative loss of hemoglobin per cell, and again is unlike nitrous oxid results, in which the only sign of a low color index is found immediately after the anesthetic mask is removed, and which is completely gone in two hours.
>
> The volume-index likewise shows an immediate loss, which is most marked in twenty-four hours, and again on the fifth and seventh days. In nitrous oxid readings, the percentage volume remained unchanged throughout.

A demonstrable anemia is produced even after a fifteen-minute anesthesia of ether that does not begin to improve until after the fifth day, and as Coburn[1] says, "such an effect as this which does not begin to improve until after the fifth day must certainly retard convalescence even in favorable cases, and in critical cases may be the determining factor in producing a fatal termination."

It has been recognized for some time that ether increases the toxemia of infection and impedes the functional activity of the leukocytes thus lessening the patient's resistance. We have been advised against administering ether to tuberculous patients, the result often being the establishment of new foci of infection or the lighting up of an old one. Is this due to the irritant properties alone, or is it more reasonable to believe that it is due to the lowered resistance produced? Further, is it not a logical deduction to make, that patients whom we believe to have no infection, and even those in the so-called simple cases for operation, should have the benefit of an anesthetic that causes no such trouble, that does not, like ether, reduce the functional activity of the leukocytes and retard Nature's forces?

C. B. Parker[2] reports 218 cases of nitrous oxid-oxygen anesthesia, of which nearly all were major operations and the subjects unfavorable for any anesthesia. Among them were patients suffering from organic disease of the heart, kidneys, and lungs, wasting and suppurative conditions, asthma, empyema, diabetes, and alcoholism, the very old and the very young; patients greatly overweight, those who had developed alarming symptoms in previous attempts with ether or chloroform, and those who had experienced the distress of previous etherization. Parker came to the conclusion that nitrous oxid was safer and more agreeable.

Peairs[3] says that "nitrous oxid and oxygen is the safest of all anesthetics; post-operative complications are less frequent," and that its more general use should be encouraged.

In the so-called "borderland" cases, those of grave infections and operations on the very ill, the consensus of opinion seems to be that nitrous oxid-oxygen anesthesia gives the chance to live and is often the hinge on which an ebbing life may turn. In the "inevitably fatal" cases, Crile says: "Not a patient showed the rapid march to fatality immediately following the operation, which occasionally follows ether."

It would seem advisable to endorse the report of the Anesthesia Committee at St. Louis in 1910, that gas in the hands of highly skilled anesthetists as a routine anesthetic is the best method yet devised, when such men as George W. Crile of Cleveland use it in from two to twelve operations every day and grow more enthusiastic in its praise as their experience increases. At a recognized medical center such as Johns Hopkins Hospital, it is in general use every day by such men as Howard A. Kelley and is advocated enthusiastically by Gatch, an authority on the subject of rebreathing, as the best and safest anesthetic.

Coburn[1] quotes Dr. Frederick Hewitt, a leading authority of London, as saying: "There is no form of anesthesia at present known which is so devoid of danger as that which results from nitrous oxid when administered with a sufficient percentage of oxygen to prevent all asphyxial complications."

When such reports come from such sources we must, it would seem, refrain from settling down with too much complacency in this regard, if not in justice to the profession, out of duty to the patients. I wish to discuss briefly the newest and what I believe to be the best method of using nitrous oxid-oxygen, namely, by rebreathing.

It has been found that in rebreathing one's own carbon dioxid during the administration of nitrous oxid and oxygen, the patient's general condition improves in every

respect, pulse, respiration and general well-being, and as an explanation for these facts I wish to quote from an editorial[4] in THE JOURNAL regarding a series of articles by Yandell Henderson of New Haven, dealing with an elaborate experimental investigation of shock from an entirely new basis.

> Briefly, Henderson believes that shock primarily is due to a diminished amount of carbon dioxid in the blood and tissues of the body. This lack of the normal amount of carbon dioxid is termed acapnia. His experimental results are most interesting and they are full of much practical suggestion to the surgeon, because they seem to show that some of the technic, commonly practiced, is based on erroneous ideas. In a short summary of this kind, necessarily only a few of the most interesting features of the work can be cited.
>
> Henderson reviews the literature of carbon dioxid as a hormone, or chemical regulator of respiration, to show that the failure of circulation and of the nervous system in shock and the cessation of respiration in true apnea must logically be referred to the same cause,—acapnia.
>
> Experiments on dogs, which were devised to bring about a sudden great diminution in the carbon dioxid content of arterial blood, resulted in an increase of the heart-rate up to the point of cardiac tetanus and death. Voluntarily forced breathing in man induces symptoms resembling shock, probably because the increased pulmonary ventilation results in an abnormally great exhalation of carbon dioxid. Pain, ether, excitement, sorrow, fear, and other conditions inducing shock, involve excessive respiration. Because a marked diminution in the amount of carbon dioxid in the arterial blood creates a lack of the normal stimulation of respiration, excessive artificial respiration in dogs for twenty-five or thirty minutes, by causing greatly increased pulmonary ventilation, is followed by a cessation of breathing so prolonged that the heart fails for lack of oxygen. During this anoxemia an acidosis occurs, owing to an accumulation in the blood of products of incomplete tissue combustion. The administration of carbon dioxid gas during the period of cessation of respiration, induces an immediate return of natural breathing; and the administration of oxygen affords ideal conditions for the prevention of the asphyxial acidosis. Anesthetics tend to prevent shock, because they diminish the excessive respiration caused by pain. The respiratory excitement during the initial stages of anesthesia, diminishes the carbon dioxid content of the blood, and thus tends to induce a subsequent failure of respiration. Similarly, ether, unless neutralized by morphin, often causes (in dogs) hyperpnea, acapnia and a consequent fatal apnea. Of particular interest in this connection are observations by W. D. Gatch in several hundred anesthesias, during which patients were allowed to rebreathe some of their own carbon dioxid. In no instance was there any evidence of shock. These observations seem to confirm Henderson's theory to a greater or less degree; and they lend evidence to his statement that "skilful anesthesia consists in maintaining the threshold of the respiratory center for carbon dioxid at a nearly normal level, and in avoiding the development of either acapnia or hypercapnia."

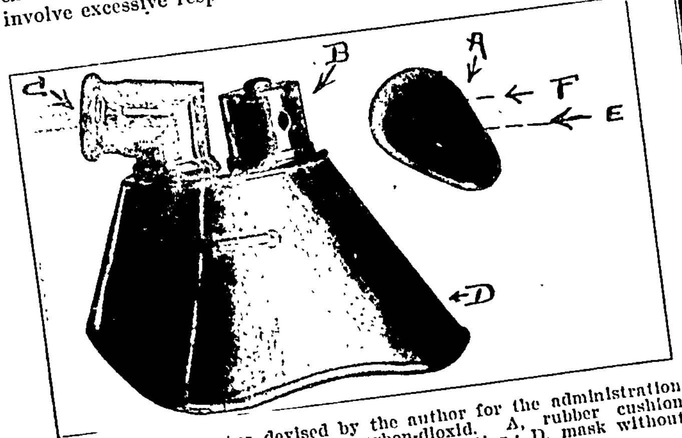

Fig. 1.—Apparatus devised by the author for the administration of nitrous-oxid—oxygen plus carbon-dioxid. A, rubber cushion (underside); B, exit valve; C, elbow connection; D, mask without cushion; E, inner aspect of B; F, inner aspect of C.

I have been using the rebreathing method for nearly a year, and have observed that the rapid pulse becomes slower, seldom faster or weaker, with an increase in the tension and the rapid respiration sometimes seen, becomes slower and deeper. No patients have shown any symptoms of shock and all have seemed improved, being in a more tranquil state of mind and without the depressing after-effects of ether.

As Gatch[5] observes, "very sick patients with a rapid pulse and quick shallow respiration actually seem benefited by this form of anesthesia." The duration of time that I have continued this anesthesia runs from five to one hundred and twenty-five minutes. It has been my practice recently to administer a hypodermic injection of morphin gr. 1/6, scopolamin hydrobromate gr. 1/150, one hour preceding the operation, and where the patient is not tranquil at the half hour, the dose is repeated. This has proved most satisfactory, giving a smoother and more relaxed anesthesia. If relaxation is not sufficient, ether is administered for five or ten minutes, returning to the gas with relaxation as desired.

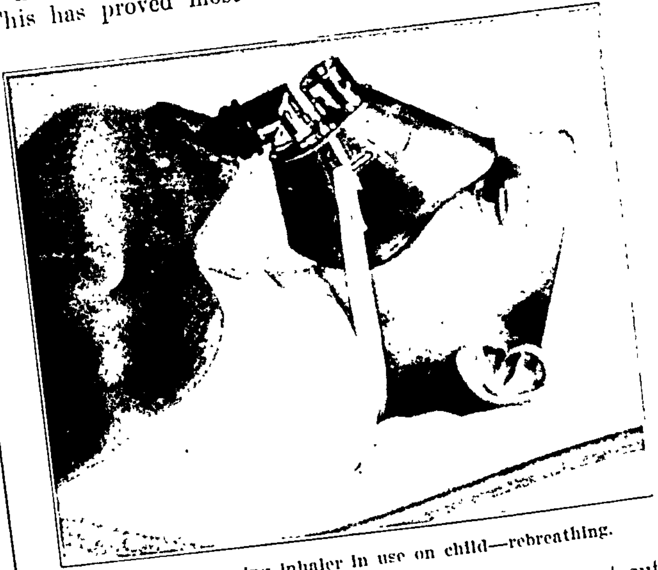

Fig. 2.—Showing inhaler in use on child—rebreathing.

The apparatus which I have devised for the purpose is shown in Figure 1, while Figure 2 shows it in actual use, held in position by an elastic tape, on a child ten years old. This also illustrates the adjustability of the rubber cushion, which is made by stretching the wrist of a rubber glove over the edge of the mask (A). The direct connection of the rubber bag to the mask allows perfect freedom in rebreathing. There is but one valve to be operated (B) and that requires but a slight turn about once every two minutes. By this exit valve the bag is emptied in five or six breaths, or at once by pressure on the bag. The elbow connection may be turned to one side or the other if the straight position shown seems undesirable. If rebreathing is not desired there is a place on the inner end of the elbow connection (which projects into the mask) to insert a little round tin float-valve (F), which prevents exhaling into the bag; when this valve is in use the valve cap (B) is left open. The rubber tube shown ends in a Y connection to a nitrous oxid and an oxygen cylinder (extra Y and cylinder may be attached if desired).

[5] Gatch: THE JOURNAL A. M. A., May 5, 1910, p. 778.

The bag is filled, ordinarily, about half full of nitrous oxid, followed by a small spurt of oxygen, sufficient, as experience teaches, to keep the color good.

I have used this apparatus successfully for about one year; it is the result of considerable experiment on my part to devise an apparatus that is light (about one pound), sterilizable, unbreakable and inexpensive.

It has been my aim to show by the experiments of Henderson on shock that the good reports on nitrous-oxid-oxygen, rebreathing, or autostimulation as it might be termed, are founded on scientific laboratory experiments, besides clinical observations, and that this anesthesia is not a mere fad to be cast lightly aside. It is surprising to find so many who are wholly unfamiliar with the progress in anesthesia and who even seem unwilling to believe that there is a necessity for improvement in the present method of using ether alone.

It is not requested that nitrous-oxygen-carbon dioxid should be accepted as a panacea for all the evils attendant on anesthesia, nor can it be expected that ether will be discarded as chloroform has been in the past, but if the clinical studies, the experimental research and the conclusions of so many eminently reliable men are considered, it would seem that but little argument could be advanced against its superiority as an anesthetic.

MYOTONIA ATROPHICA

WITH A REPORT OF TWO CASES

FOSTER KENNEDY, M.D., B.Ch. (Queen's)
Chief of Clinic, Neurological Institute
AND
C. P. OBERNDORF, M.D.
Clinical Assistant, Neurological Institute
NEW YORK

The symptom-complex to which Rossolimo[1] gave the name of "myotonia atrophica" is not only an extremely rare disease, but apparently is exceptionally uncommon in America, the two cases reported in 1908 by Ramsay Hunt[2] being the only ones on record. Batten and Gibb,[3] in 1909, collected reports of all the cases which had been described under various titles up to that time, which showed the rather definite clinical picture of myotonia atrophica. They were able to enumerate twenty, and as a result of their study state the following as the cardinal symptoms of the disease:

> 1. Weakness and wasting of the following muscles, viz.: the orbicular muscles of the mouth and eyes; the temporals and masseters; the vasti muscles of the thighs with the recti femuris frequently escaping completely; the muscles of the anterior tibial groups, resulting in bilateral foot-drop.
>
> 2. The myotonic phenomenon evidenced more particularly by a marked difficulty in extending the fingers from a flexed position. The muscles show a diminution of irritability to the faradic current and, to a lesser degree, to galvanic stimulation as well. Certain cases show in localized muscle groups a modified myotonic electrical reaction, namely a slow contraction and slow relaxation to both forms of electricity.
>
> 3. The deep reflexes are depressed according to the degree of wasting in those muscles necessary for their production.

There is apparently a frequent tendency for the disease to take on familial characteristics, but this is by no means constant and was not observed in either of our cases.

Case 1.—*History.*—A clerk, G. S., aged 35, was admitted March, 1911, to the out-patient department of the Neurological Institute, in the service of Dr. Fraenkel, by whose courtesy we are enabled to report on the case. The patient complained of weakness in the legs which, however, was not sufficient to produce extreme disability in walking. (He had just walked over one and one-half miles to reach the hospital, and was by no means greatly fatigued.) Two years before coming under observation, he noticed that he was more easily made tired than usual, especially by going upstairs, in doing which it became necessary for him at all times to make use of the bannisters. Later he found that he frequently tripped against small obstacles in his path; in stepping from the roadway to the pavement, he would fail to raise his foot sufficiently to clear the edge of the latter, etc., and the gradual onset of double dropped foot at last produced the characteristic steppage gait suggestive of a high-stepping horse. The patient's general health remained perfect; he had no pain or paresthesiæ; no sphincter trouble, nor at any time any difficulty with vision. Nevertheless, his condition was stated by two or three medical men to be due to incipient tabes dorsalis. His visit to the Neurological Institute was more the result of his wish to be cleared of what he considered to be the unjust charge of antecedent lues than of the hope of cure of his present disease. He had had measles, whooping-cough and a severe attack of scarlet fever in early childhood. During adolescence and early manhood, he had had three separate and serious attacks of diphtheria. Nothing of a neuropathic nature could be discovered in his family history. He was an only child; his mother was alive and in good health, while his father had but recently died of pneumonia at a fairly advanced age.

Examination.—The patient was seen to be a small, poorly built man with the worn mask-like expression characteristic of the myopathic facies. There was no defect of any of the special senses. The movements of the eyeballs were perfect, but there was very marked weakness of the orbicular eye muscles so that the lids were drooped and the eyes could be closed only feebly. The pupils were normal. The temporal fossæ were scaphoid, appearances produced by the complete atrophy of the temporal muscles. The mouth was lax and patulous. The masseters were below normal in size and power, and the strength of the movements of the jaws was distinctly poor. The sternomastoid muscles were completely atrophic, and were represented in each case by a thin fibrous cord. The abolition of these muscles threw the sternal ends of the clavicles into unnatural prominence, together with the other neck muscles which were quite unaffected. The biceps, triceps and deltoid muscles of both arms were weak and considerably wasted. The muscles of the hands and forearms were of normal bulk and power, but it was found that the patient had remarkable difficulty in relaxing the grasp of either hand—an expression of muscular hypertonus which could not be elicited elsewhere in the body. The trunk muscles were normal. In the lower limbs the internal and external vasti muscles were wasted, though there was complete retention of the rectus muscle of each thigh. The anterior tibial muscles and the peronei were wasted on either side so that a condition of bilateral incomplete foot-drop had resulted. There was no sensory change. The triceps and biceps jerks were diminished while those of the wrist were fairly brisk. The abdominal reflexes were equal on the two sides. The knee-jerks were present but equally depressed on the two sides; the ankle jerks could not be obtained. The plantar reflexes were of the normal flexor type. Electrical reactions: the intrinsic muscles of the hands and those of the forearms showed slow contraction and slow relaxation to both faradic and galvanic currents.

Case 2.—*History.*—The patient, J. F., a Russian Hebrew who had lived for many years in the United States, by trade an insurance agent, was also in Dr. Fraenkel's service at the Neurological Institute. He presented a family history exceptionally free from influences which might be regarded as bearing on the development of his condition. Both his paternal and maternal grandparents showed unusual longevity, while of his nine brothers and sisters, eight had reached a medically uneventful middle age and the ninth had died as the result of an untreated strangulated hernia. He himself, a married man of 43, of temperate habits, had suffered from no illness with the exception of occasional gastric disturbances, until the onset of the disease for which he presented himself at the clinic. About March, 1908, the patient fell as he was alighting from a street-car, striking heavily upon his right knee and fainting as a result of the accident. He asserts that the trauma to the knee-joint was sufficiently severe to confine him to bed for six weeks, but immediately on arising, he began to perceive a weakness in the right leg which became progressively worse so that he would stub his toe in walking. Simultaneously a cataract began to develop in the left eye; this was subsequently removed. The patient next noticed in turn a diminution in power in the right forearm, the left extremities and, finally, in the muscles which supported the head. The symptom for which the patient sought relief most urgently was an intense fatigue, which, coupled with his loss of power in the extremities, had prevented his working for over a year. He expressly emphasized that at no time had he experienced pain, though of late he suffered great annoyance through weakness of the muscles of deglutition, a diminution of sexual power, and a clouding of vision in the right eye. The sheer effort of undressing in the clinic caused him to perspire profusely and drop back to the couch exhausted, an evidence of the extent to which the disease had progressed.

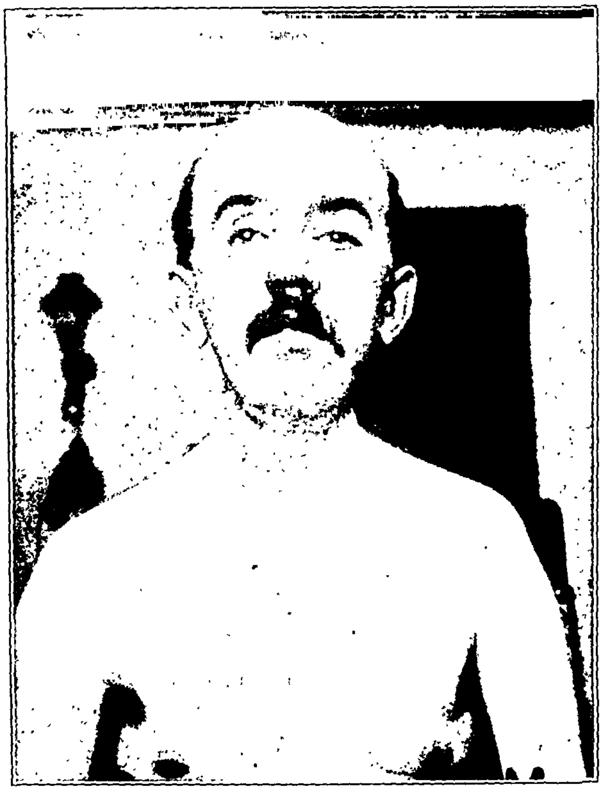
[2] Hunt, J. Ramsay: Jour. Nerv. and Ment. Dis., 1908, p. 269

[3] Batten and Gibb: Brain, 1909, p. 187.



Case 1. G. S., showing hollowed-out temporal fossæ, myopathic facies with dropped eyelids and patulous mouth. Absence of sternomastoid muscles.

Examination.—Physically the patient was a moderately emaciated, small, stooped man, whose face showed a peculiar lack of expression, which, without being particularly stupid, seemed vacant, lifeless and tired. He walked with a typical steppage gait, the very effort of which exhausted him so severely that the act appeared laborious. He spoke in a slow, monotonous and subdued tone which produced the impression of tired vocal muscles. The wide, artificially produced irregularity of the left pupil prevented a normal reaction to light, but in the right eye, though reflected light disclosed a beginning cataract, the pupillary response to both light and accommodation remained brisk. The tendon reflexes showed both triceps jerks absent, but the supinator jerks faintly present Both quadriceps contractions were quite well preserved, but a right Achilles jerk was only faintly retained and the left Achilles could not be elicited. Neither Babinski's sign nor ankle-clonus was present. Epigastric, abdominal and cremasteric reflexes were actively responsive. Sensation was normal The muscular system revealed myotonia present when the patient made a fist with his left hand. The fingers were relaxed so slowly from the closed position that the patient's hand dropped away from the hand he grasped before his own became fully extended, but after repetition of the movement this difficulty rapidly disappeared. The left side of the face seemed even more relaxed than the right, though the following facial muscles were markedly wasted on both sides, viz. the temporals, producing hollows in the temporal fossæ; the levators palpebræ, causing the lids to droop heavily; the masseters, permitting the cheeks to sink inward and making it difficult for the patient to chew solid food, and the orbicularis oris, which gave a weak expression to the mouth. Perhaps the most striking feature in the whole picture was the total absence of the sternocleidomastoids, but the trapezii were also considerably involved, while the practically total obliteration of the triceps caused the biceps to appear almost hypertrophied by contrast. The extensors of the forearm, especially the left, were weak and flabby. The muscles of the trunk and abdomen had escaped, though both recti abdominalis seemed somewhat relaxed. This weakness, however, was not sufficiently grave to prevent the patient from raising his body from the recumbent position, provided that his head was supported when he made the attempt. In the lower extremities the adductors of the thigh were somewhat weaker than the abductors, and in the leg on either side the tibialis anticus and peronei showed great atrophy. The electrical examination made by Dr. J. W. Stephenson resulted as follows: "There was no complete reaction of degeneration in any of the muscles examined, but with the exception of the right biceps and the flexors and extensors of both forearms, all the muscles showed some alteration of reaction, namely, there was an atypical myotonic reaction. Both triceps, trapezii and deltoids gave no faradic response. These, with the left biceps, showed decreased excitability to galvanism."

While the first of our cases conforms exactly with the clinical picture drawn by Batten and Gibb, it is to be noted that in the second case there occurred in addition an intense muscular weakness and premature bilateral cataract. The former condition is explicable by reason of the advanced stage of the disease, while in regard to the latter it is interesting to note a remarkable family of thirteen members mentioned by Greenfield,[4] of whom six were healthy, two had premature cataract, three myotonia atrophica, and two suffered from both conditions. In view of such a striking and persistent combination of these two conditions it would seem that the association of cataract with the symptoms-complex under discussion is more than accidental and would suggest that both may be abiotrophic in character.

Infant Mortality.—Dr. Jacobi of New York recently gave statistics showing that the industrial conditions in many of our communities are largely responsible for our unnecessarily high infant mortality: "Women working at home are very often worse off even than their sisters in the factory. Their constant treadling of the machine undermines their health. Seamstresses develop anemia, tuberculosis and pelvic diseases. Cigarmakers who work at home develop consumption to the extent of 90 per cent. Such women living in dirty dwellings, without air or light, bear children that are starved before they are born—who are infected with hereditary disease—and are destined either to perish miserably, or, more miserably, to populate asylums, hospitals and penitentiaries."—C. S Sheldon in *Bulletin American Academy of Medicine.*

THE IMPORTANCE OF THE QUANTITATIVE REGULATION OF THE DIET[*]

H. D. ARNOLD, M.D., and
R. C. LARRABEE, M.D.
BOSTON

It will generally be admitted that modern methods of infant-feeding have been of very great benefit. It is one of the very few accomplishments in dietetics that the profession may point to with pride. Yet it differs from the older methods of milk feeding chiefly in the fact that the nutritive ingredients of the milk are regulated quantitatively with greater accuracy.

Our grandmothers used to dilute cow's milk in giving it to infants. Their object was to make the milk "less rich" and more digestible, with fewer "curds." They were in reality lowering the percentage of protein, which in cow's milk is too high for infants. Then they sweetened it, apparently to make it more acceptable to the taste. But this also fulfilled the very desirable object of increasing the carbohydrates, which are low in cow's milk as compared with human milk. And further, if the baby did not gain in weight they used "richer" milk, that is, they increased the percentage of fat in the milk mixture, thus adding materially to its nutritive value.

So "modified milk" and "percentage feeding" are not new methods—for milk was always modified—but they represent the introduction of accuracy in the quantitative regulation of the infant's food. It has accomplished so much that at first sight it seems hard to believe that the great advance in infant-feeding is based essentially on so simple a thing as greater accuracy, yet this really is the case. The explanation lies in the fact that this accuracy permits the physician to regulate the amounts of the different foodstuffs—protein, fats and carbohydrates—which comprise the nutritive part of all food. He can do this with sufficient accuracy to allow him to study the effects of such modification of the amounts of the different foodstuffs, and to adapt the diet intelligently to meet the requirements of the individual case. The method needs no defense from us; our object is to use its well-known success as an argument for the extension of the same principle to other fields—to the regulation of the diet of adults in all cases in which greater accuracy will be advantageous.

In general, the regulation of the diet of adults by physicians is not a matter in which the profession can take much pride. With a few directions of "Do take this" and "Do not take that"—the selection of the foods being largely regulated by tradition based on empiricism—the physician leaves the rest to the patient's appetite and the judgment of a nurse or some lay person. This is equivalent in infant-feeding to the direction: "Feed the baby milk"—leaving all other details for the family to work out. It is essentially an absurd position, which is perpetuated by two factors. One is the lack of appreciation by physicians of what may be accomplished by more scientific diet regulation; the other is the difficulty of its application in their hands. This is due largely to the fact that the present generation of physicians was not taught the fundamental facts with any reference to their practical application. This latter defect will soon be remedied, for the importance of the scientific regulation of the diet is being more fully recognized by the profession. The medical schools are beginning to give instruction along these lines, and the coming generation of physicians will be prepared to utilize these valuable measures fully. Even now its value in the treatment of disease has been proved, and an important question for the older physicians to decide is whether they will "keep up with the procession" by adopting this advance in dietetics, or will wait for the more efficient youngsters to crowd them to one side.

You need but to mention the word "diabetes" to the wide-awake physician of to-day and he will recognize that these remarks apply to this disease at least. He knows that the most successful treatment of this disease is based on the careful quantitative regulation of the amounts of carbohydrates allowed in the diet, combined with such an adjustment of the other foodstuffs as to furnish sufficient nutriment for the needs of the system.

The old haphazard methods of treating this disease are no longer justified. Our duty to our patients demands the quantitative regulation of the amount of carbohydrates given in the treatment of diabetes, and the recognized importance of this measure is again cited by us as an argument for the extension of this measure over a wider field.

It has not so generally been recognized that the proper regulation of the amount of protein in the food is almost as important in the treatment of nephritis as is the regulation of the carbohydrates in diabetes. Yet, all will admit that the fundamental principle of the treatment of this disease is to spare the kidneys from unnecessary work. Since one of the chief functions of the kidneys is to eliminate the waste products of nitrogenous metabolism it necessarily follows that we can secure this result best by limiting the amount of the nitrogenous material, or protein, that is taken in the food. This matter has been emphasized by Von Noorden and others, and an article by one of us, delivered before this Section last year, dealt with this matter at length.[1]

A further reason for the quantitative regulation of the diet in diabetes and nephritis is the fact that it is not only necessary to reduce the amounts respectively of carbohydrates in the one case and of protein in the other, but that it is of equal importance to make sure that the patient is getting a diet of sufficient nutritive value to meet the requirements of the system for heat and energy and to offset tissue waste. Unless this is provided for we add insufficient nutrition or partial starvation to the condition of disease already existing. This can best be determined by a calculation of the caloric value of the diet. In order to ascertain this we must know with some approach to accuracy the amounts of food taken, which is another way of expressing the quantitative regulation of the diet.

In another field this same consideration holds. Whenever the heart is affected the question of a sufficient supply of nutriment to enable it to maintain its strength is of vital importance. Unless there is sufficient nourishment the heart-muscle will weaken, and disastrous results will follow. This is of the greatest importance in the so-called reduction cures for obesity. If in these cases the heart is not strong, as is often the case, serious and even fatal damage may be done to the heart by cutting the food down too far or too rapidly. In such cases the reduction can be done safely only when the nutritive value of the diet is followed closely. Furthermore, it hardly needs to be argued that in any system for reducing the weight the quantitative regulation of the diet will enable the physician to study the case more intelligently and to get more satisfactory results than if this measure is neglected. This is true whether there is any danger from the heart or not.

---

[1] Arnold, H. D.: The Importance of a Low Protein Diet in Chronic Nephritis, The Journal A. M. A., Dec. 24, 1910, p. 2193.

In many cases of apparent neurasthenia and debility or malnutrition we have found that a calculation of the diet not only helps in the understanding of the case and in the diagnosis but points the way to treatment and enables us to give a more accurate prognosis.

It is interesting to note that recently the diet in cases of tuberculosis has been the subject of extensive study from this point of view. It has been proved that patients do as well or even better when such study and quantitative regulation provides a well-balanced diet, with an abundant but not excessive amount of nutriment.

In gout and those forms of rheumatism in which metabolism is at fault the quantitative regulation of the food is important. These conditions are not as yet as well understood as we might wish in these respects, but this method will enable us to give more scientific consideration to the problems which these diseases bring up. In this way we may hope for a better chance for a successful solution of these problems. In both diseases the cutting down of the protein of the diet seems advantageous, and in gout that careful regulation of those articles of food that contain purin bodies, which is an essential feature of the treatment, can best be secured by the quantitative regulation of the diet.

We have pointed out a number of conditions in which the quantitative regulation of the diet will be of aid and in many cases it is essential to successful treatment. Few will deny the desirability of such measures. The question arises whether it is practicable in application. In order to carry out these measures we must know with some accuracy the composition of food and we must understand a few of the fundamental principles of dietetics. Fortunately, the more recent books on treatment have taken up these matters in some detail. With some patience and study the matter can be worked out. In many of the diseases mentioned, the text-books or monographs will give the desired information. At first, the work is difficult and time-consuming, because it is new and is more or less complicated, but familiarity soon brings facility, and the results well repay the time and trouble involved. We have used the diet chart prepared by one of us (Arnold) in practice for several years and have found that it simplifies the problem a great deal, and makes it feasible to do this work in private practice satisfactorily, when once the physician is conversant with the method of its use. We have repeatedly found that an intelligent nurse can use these charts not only to record, but to calculate the diet, and this has been done also by intelligent members of the family of the patient. Such reports enable the physician to follow his case with little trouble and to handle it much more intelligently. These charts are published by the W. B. Saunders Company. They are not essential for this work, for all that is essential is for the physician to get his data from any reliable source and he can apply them in any convenient form. Such charts merely bring convenience in such methods. With such an aid we have found it perfectly feasible to carry out this work in practice. From an extended experience with this work we can say with confidence that it is well worth while in any condition where the diet enters as an important factor in treatment. By such means we raise dietetics from unintelligent empiricism to a fairly satisfactory scientific basis.

427 Beacon Street.

ABSTRACT OF DISCUSSION

Dr. Wilder Tileston, New Haven, Conn.: The quantitative regulation of the diet is of extreme importance in the treatment of all conditions of undernutrition and obesity. It is not at all difficult to regulate the diet in this way if one obtains tables showing the nutritive value of foods. Such tables can be obtained from Bulletin 28 of the Department of Agriculture, on the payment of 10 cents. The principles governing the diet of the ill are frequently misunderstood and misapplied—more so than other principles in medicine.

THE THYROID WITH SPECIAL REFERENCE TO HYPERTHYROIDISM AND A NEW METHOD OF TREATMENT

MILES F. PORTER, M.D.
Surgeon to Hope Hospital; Professor of Surgery in the Indiana University School of Medicine
FORT WAYNE, IND.

The surgical treatment of exophthalmic goiter is based on the hypothesis that the symptoms are due to hypersecretion, or hyperabsorption, or both. In the present state of knowledge concerning the chemistry of the secretion of the thyroid and other ductless glands, this is the best working hypothesis. It is probable, rather than possible, that in the near future we may have specific serums to counteract the various symptoms of thyroid disease, but until we know more than we do now, we can do no better than to work on the theory above given.

Ligation of one or more of the thyroid arteries has proved of benefit in some cases, but in the main the results have been disappointing. If one recalls the arterial supply to the thyroid, one ceases to wonder that this treatment has not proved satisfactory. Ligation of the common carotid does not affect the function of the brain, and, if a sufficient interval is allowed to elapse, both common carotids may be ligated without interfering with the function of the brain. The analogy between the arterial supply of the brain and the thyroid is very close.

Pole ligation, as first suggested by Stamm, would seem to be, theoretically, a more effective operation than arterial ligation, because it at once cuts off a part of the blood-supply to the gland, and a part of the return flow of both blood and lymph, presumably laden with toxic material. Moreover, Stamm's operation produces a greater anemia by virtue of the fact that it reduces the possibility of perfect and prompt reestablishment of the circulation by anastomosis. Ligation of the accompanying vein and artery at the same time should be, and I think is, more effective than ligation of the artery alone, but not so effective as the Stamm operation for the reason that the latter does all that the former does in way of curtailing the circulation of the blood in the thyroid and in addition puts out of commission permanently that portion of thyroid between the double ligations and occludes also the lymphatics of the ligated pole. It has not, however, been employed in a sufficient number of cases to enable one to speak accurately of the results obtained.

Partial thyroidectomy is the most effective treatment we have up to date. This, however, is a major operation and largely because of this fact patients are not subjected to this operation until other treatment has been tried and failed, and the disease has rendered the subject a substandard operative risk. Many of these patients must first be subjected to preliminary rest treatment coupled with one or more ligations before thyroidectomy can be done with reasonable safety. Again, in many of these patients, operated on late, myocardial and other changes which are permanent have already taken place.

Ochsner and Thompson name nine dangers of thyroidectomy: (1) anesthesia; (2) shock; (3) hemorrhage; (4) hyperthyroidism; (5) infection; (6) recurrent laryngeal nerve injury; (7) injury to parathyroid glands; (8) air embolism; (9) collapse of trachea and consequent asphyxia. To these should be added a tenth, namely, myxedema. It is quite plain that a simple, safe, and effective operation for hyperthyroidism is much to be desired. I believe that injection of boiling water into the gland will fulfil this desire.

While my experience with this method up to date is not sufficient to put it on a firm basis, yet it is enough, I think, to warrant this belief. The method was first used in dogs to demonstrate its safety and its efficiency in destroying normal thyroid tissue and goitrous tissue. These experiments were made for me by my former assistant, Dr. H. K. Mouser, now of Oakwood, Ohio. I have now treated four cases as follows:

Case 1.—An unmarried woman who was troubled with a goiter was referred to me by Dr. McCaskey in whose hands she had failed to improve under ordinary treatment, so he asked me to inject the goiter with hot water. She had a small bilobed goiter. Into each lobe was injected 40 minims of boiling water. She was asked to remain in bed for a few hours after which she was allowed to get up and be about. In a few days she left the hospital. One month after the operation, she came to the hospital for examination. I saw her a few moments after her arrival. Her pulse was 80, regular and of good volume. She expressed herself as feeling well and she had gained in weight. She said she was able to do her housework and was having no difficulty with her heart. Prior to the injection of hot water she complained much of palpitation of the heart and her pulse at that time varied from 80 to 120. She was to report to either Dr. McCaskey or me in case there was any relapse. Neither of us has heard from her.

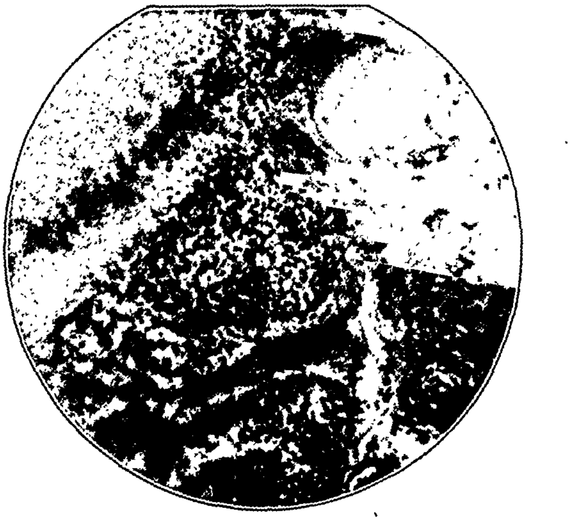

Fig. 1.—Case 4 (J. H.). Section after the injections of boiling water, showing connective tissue proliferation and compression of parenchyma. × 265.

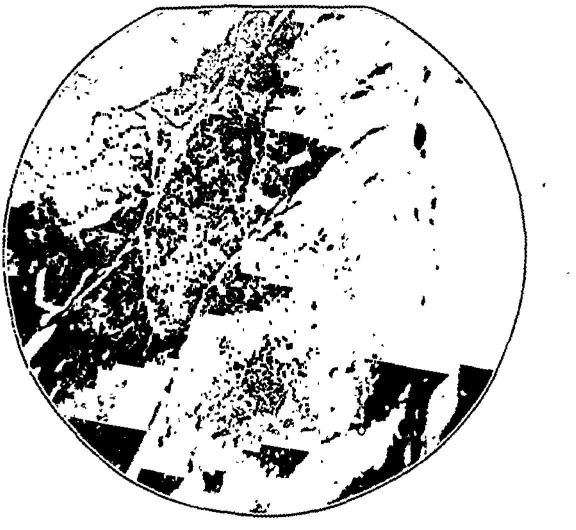

Fig. 2.—Same as Figure 1. ×55.

Case 2.—This was a mild case in a male patient referred by Dr. McCaskey. This patient went to work within seventy-two hours after one treatment and was still at work and symptomatically cured a few weeks ago, though he still has a small goiter.

Case 3.—*Patient.*—Mrs. Z., aged 48, married. Family history was negative. She had had typhoid twelve years ago; appendectomy and gall-bladder drainage two years ago. Menses came at 12, always irregular and painful. Patient came to the hospital on a cot on May 14, 1911, having been in bed two weeks. She complained of alternating constipation and diarrhea; pain and tenderness over whole abdomen especially the right half. She had a great deal of headache; was "short of breath" at times and had "dizzy spells"; was very nervous.

Examination.—The chest, abdomen and pelvis were negative, except for general abdominal tenderness. There was no rigidity. There was a perceptible bilobed goiter, larger on left; slight tremor. Examination of stools, urine and blood negative. The patient was kept in bed on light diet.

Treatment and Result.—After five days observation, during which time her pulse ranged from 68 to 84, the patient was given 5 grains of thyroid every four hours. After taking the thyroid for twenty-four hours her usual symptoms were exaggerated and in addition she complained of sleeplessness. The thyroid was continued, however, for six days when she complained of being "short of breath" and her pulse which was small and irregular, ran from 85 to 115. The thyroid was now stopped. Two days later the patient was feeling better and sat up for a few hours. While up her pulse was 108 and rather weak. Thyroidectin was given with negative results for three days, when her goiter was injected with 50 minims of boiling water. There was no reaction but she was kept in bed a few hours after the injection. Five days after the injection she was discharged. Dr. Drayer later reported her much improved and on July 12, forty-two days after the injection, she came to my office. The thyroid could not be seen, save on close observation; the pulse was regular, good volume, 80 per minute. There was no tremor. The patient said that she was attending to many of her duties and was much better in every way, though she felt the need of a little rest on the sofa almost every day.

Case 4.—*Patient.*—J. H., female, aged 27, single. Family and previous personal history unimportant. Her normal weight was 142 pounds. When I first saw her, she weighed 89 pounds and presented all the symptoms of exophthalmic goiter in the most aggravated form it has ever been my privilege to see, including exophthalmos, tachycardia, shortness of breath, trembling, diarrhea, nausea, insomnia and loss of appetite. She was in a reclining chair when this examination was made. The pulse was irregular and weak, from 160 to 180 per minute. She was admitted to Hope Hospital July 27, 1910.

History.—The following notes are taken from the records made at the hospital: The patient has been aware of an enlarged thyroid for five months, and has been aware for that time that she had exophthalmic goiter. For two years, however, she has been losing weight and during this period has suffered from severe headaches. The eyes have been prominent for four months. The patient has been under treatment for two months and for the past week has been taking thyroidectin; has not menstruated for six weeks. Examination after several hours in bed disclosed, in addition to the above, a dilated heart, a large firm thyroid with a pronounced thrill especially in lateral lobes. Neck measurement 15⅛ inches. Marked exophthalmos; eyes remain partially open during sleep, and cannot be closed entirely without strong effort. Urine normal. Small irregular dicrotic pulse 146 per minute, systolic pressure 180, diastolic 155. Temperature 99 3/5 F. Abdominal examination negative.

Treatment and Result.—The patient was given no treatment except injections of boiling water into the thyroid and rest in bed. For a few days only her diet was restricted on account of the diarrhea and nausea; after this she was fed liberally, including meats.

After the first two or three injections she was allowed to read in bed and do fancy work, and later to sit up, have visitors, have tub baths and visit other patients in the hospital whom she knew.

After the first two or three injections improvement was noted in her appetite, she slept better, was less nervous, breathed better, digestion seemed perfect and she no longer complained of palpitation. The pulse gradually improved in quality but did not diminish much in frequency. The thrill in the thyroid largely disappeared and there was some improvement in the exophthalmos. As she improved, she was given more liberty as to exercise, and was finally allowed to go home on Dec. 21, 1910, for the holidays, where she remained until Feb. 21, 1911. During her stay at home she took moderate exercise each day, went shopping and enjoyed the festivities of the season in a moderate way. Of course, on account of the condition of the heart, she was enjoined against exertion. She was weighed ten days after the third injection, when it was found she had gained four pounds. This gain in weight continued. When she left for the holiday vacation she weighed 120 pounds, and during her vacation she continued to improve notwithstanding the increased amount of exercise and excitement. She came back to the hospital Feb. 21, 1911, was given two more injections and discharged seventeen days later, weighing 145 pounds and expressing herself as "feeling fine." Dr. E. J. McOscar, who had seen the patient a number of times, was present at the last injection and remarked at the improvement, including the exophthalmos. I regret that I did not have photographs taken before the injections were begun, after they were stopped, and after the thyroidectomy to show the condition of the eyes and neck at these various stages of the treatment, but I hesitated to ask a sensitive girl for this privilege.

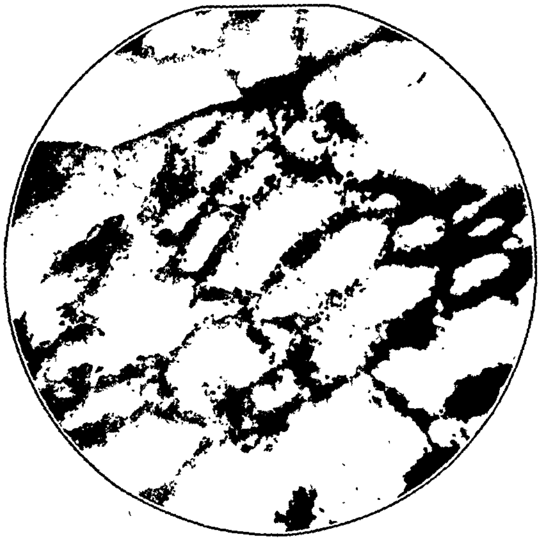

Fig. 3.—Section from gland of J. H., showing cytolysis. ×265.

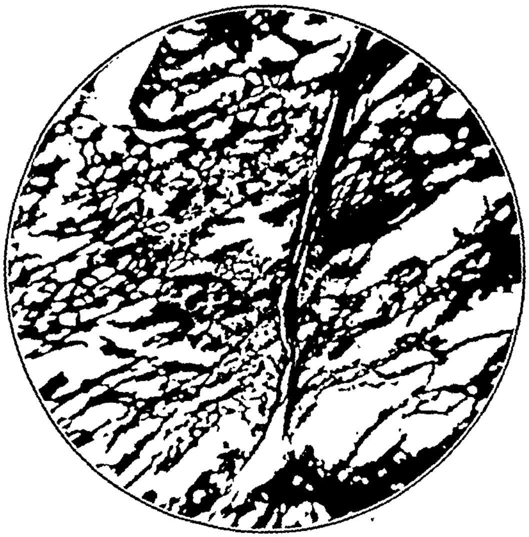

Fig. 4.—Same as Figure 3. ×55.

Notwithstanding her increase in weight, her neck had *diminished in circumference 0.5 inch.* She menstruated normally on March 10, 1911, which was the first menstrual flow she had had since June, 1910—nine months. She has menstruated regularly since.

In all, this patient had injected into her goiter 1,525 minims (a little more than 3⅛ ounces) of boiling water. There were nine seances, and at each seance from one to three injections were given. The largest amount injected at one point was 160 minims and the smallest 80 minims. The largest amount injected at one seance was 370 minims. After each injection, the patient was asked to remain perfectly quiet in bed for three or four hours. Inasmuch as the other patients whose goiters I had injected, before this patient was injected, had complained but little of the pain, the first injection was made in this case without any anesthesia of any kind. The patient complained quite loudly of the hot needle in the skin, and thereafter this was overcome by Schleich's infiltration-anesthesia at the points where the needle was to be thrust through the skin. No attempt was made to anesthetize anything but the skin because the heat is complained of only in the skin, and for the further reason that I believe that the infiltration of the gland tissue would diminish the effectiveness of the injection of hot water, or perhaps defeat its purpose entirely. *After the use of the Schleich, the only complaint made was a feeling of distention which at times caused pain to radiate to the back of the head and neck.* The excitement produced by the anticipation of the treatment, together with the pain, caused some acceleration of the pulse, and for a few hours after the treatment there was noted a rise in the temperature varying from ½ to 2 degrees F.

A minute eschar was produced at the site of each needle puncture but no permanent scar was produced. After each treatment the needle punctures were covered by pledgets of cotton saturated with alcohol and over these an ice-bag was placed for an hour or so after the patient was put to bed. When the patient was discharged, she still had pronounced exophthalmos, a good-sized goiter, a dilated heart and rapid pulse. The pulse counted for a week, at the time of her discharge, and averaged with a like count taken when she first entered the hospital and while she was at absolute and constant rest, showed a rate of 123 per minute in both counts. However, the count taken first represents the pulse while she was living a more or less active life as indicated by the foregoing report. Moreover, the pulse when discharged was regular, of better quality and no longer "went crazy" on the slightest excitement or movement as was the case when the patient began treatment.

I explained to the patient that I regarded her as cured in so far as a cure was possible, except that the tumor could be removed, inasmuch as I regarded the heart and eye conditions as manifestations of permanent tissue changes. She was told.

however, that she could have a thyroidectomy done with very little risk, in case she wanted to get rid of the deformity.

She concluded to rid herself of her "big neck" and for that purpose reentered the hospital May 14, 1911, and a thyroidectomy was done under ether anesthesia two days later. There was nothing worthy of note in the operation, save that there were numerous dense adhesions between the capsule and overlying fascia, due *no doubt to the injections of hot water*. The convalescence was uninterrupted until the end of the fourth day, when the patient began to develop a left hemiplegia, which became complete by the sixth day after the operation. She left the hospital thirty-six days after the operation with the wound healed, save a small point of granulation at the place of exit of the drains, able to walk and use the hand and arm, and with no trace of facial paralysis, though the arm and leg had not yet recovered entirely. Her breathing at this time was better from relief of pressure on the trachea. The exophthalmos and heart remained the same except that the action of the latter was improved as indicated by the improvement in the pulse, which was of fairly good quality and 100 per minute while sitting. The blood-pressure taken three days after the operation was 150 mm. maximum systolic, and 125 mm. maximum diastolic—a diminution in both diastolic and systolic pressure of 30 mm. as compared with the pressure before any treatment was instituted. Owing to an error or misunderstanding the blood-pressure was not recorded when the injection treatment was stopped.

I visited the patient at her home June 30, six weeks after the thyroidectomy, and found her much improved so far as the paralysis is concerned. There was also quite a little improvement in the heart's action and the exophthalmos. Pulse, sitting, 96 per minute.

I was mistaken in my opinion that the thyroidectomy would do her little or no good save to rid her of her deformity. She still had, after the injections, some overactive thyroid tissue which was removed at the operation. This is proved by the clinical symptoms and also by *microscopic appearance* of the removed gland.

The prevailing picture, from a number of sections made for me by Dr. Rhamy, the pathologist of Hope Hospital, is one of connective tissue proliferation with compression of the gland structure. With the high power some of the fields are almost entirely occupied by connective tissue (Figs. 1 and 2). Here and there, however, is found pronounced cytolysis which is present usually in the severest forms of Graves' disease (Figs. 3 and 4). Rarely may be found a field in which a few follicles present filled with unstained colloid and in which there is some epithelial proliferation indicating a hyperactive gland (Figs. 5 and 6).

An extremely interesting incident in Case 4 was the hemiplegia which, it will be recalled, came on gradually and became manifest first at the end of the fourth day after thyroidectomy. I have communicated with a number of surgeons with large experience in goiter work and none of them report a similar accident, nor can I find a like case in the literature. I am of the opinion that the hemiplegia was the result of cerebral hemorrhage due to arterial degeneration produced by the prolonged thyroid intoxication. In this opinion I am supported by Drs. G. W. McCaskey, A. J. Ochsner, G. W. Crile and C. H. Mayo, to whom I submitted a report of the case. It should be stated here that there could be found in the case no evidence of specific infection either inherited or acquired. In all I have injected boiling water into hyperactive goiters twenty-nine times, in four patients. From 40 to 160 minims were injected at each point. From one to three points were injected at each sitting. The largest amount injected at one sitting was 370 minims. Marked improvement promptly followed the injections in every case. No untoward results followed the injections in any case. As stated in the earlier part of this paper, the evidence thus far accumulated concerning this method of treating hyperthyroidism is not sufficient to base definite conclusions on, but it seems sufficient to warrant a more extended trial.

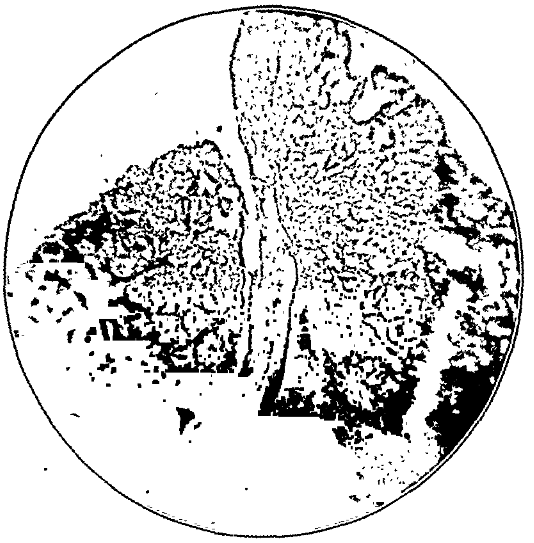

Fig. 5.—Gland of J. H., showing some hyperactive tissue after the injections of boiling water. ×55.

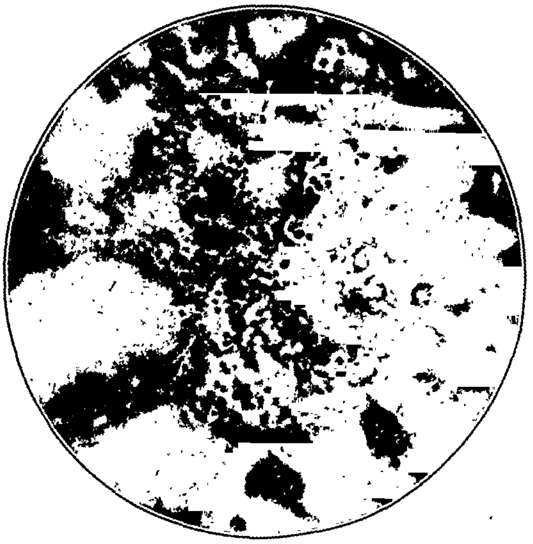

Fig. 6.—Same as Figure 5. ×265.

To me this treatment seems especially adapted to the very mild and the very severe cases. The mild cases, it seems, may be promptly cured and the severe ones, if not cured, rendered safe operative risks. It may be well to say that the injections must be made within the capsule, avoiding the immediate vicinity of the parathyroids and recurrent laryngeal nerves, and with the same general precautions that govern the boiling water treatment of angiomata.

Long and Short Incisions.—Be not proud of an extremely short incision. A longer one, in reason, will heal as quickly, to an hour. Daylight is safer than fumbling in the dark.—Robert H. M. Dawbarn, in *Medical Record*.

ACCESSORY OR ABERRANT PANCREAS, WITH REPORT OF A CASE

BENJAMIN BROOKS FINKELSTONE, M.D.
BRIDGEPORT, CONN.

While an accessory pancreas is not very rare, still it is unusual enough to warrant the report of another case. This case, like Opie's, is an accessory pancreas entirely separated from the normal pancreas and adherent to the intestine, with numerous branches of the duct of Wirsung through the section, and it is, of course, natural to conclude that the main duct must have eventually opened into the intestine.

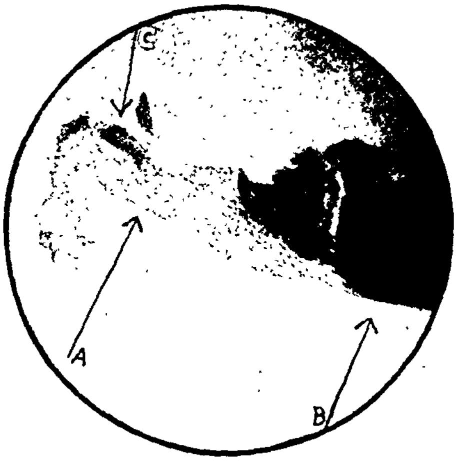

Fig. 1.—Relation of pancreas to the intestine. A, peritoneal surface of small intestine; B, aberrant pancreas inclosed by a slight capsule of connective tissue; C, mucous membrane of small intestine. Low-power lens.

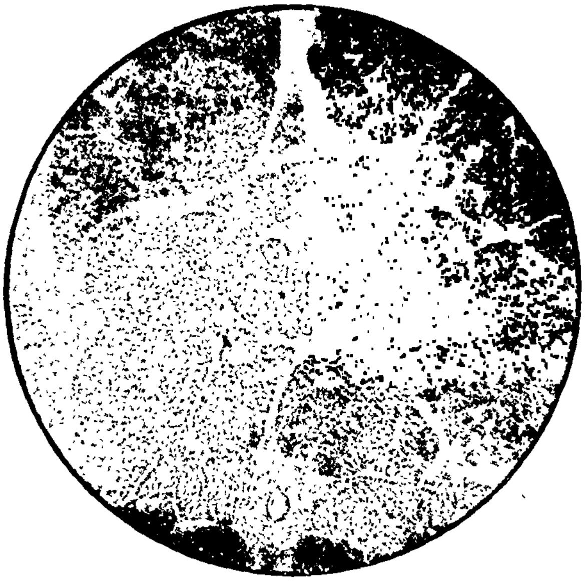

Fig. 2.—A section of pancreas showing general lobular arrangement of the organ.

Among the other cases reported are those of Klob, who demonstrated and cited two examples, viz., one embedded in the wall of the stomach, while in the other case it occupied the wall of the jejunum. Zenker collected six examples in which in every case the tumor had a duct entering the intestine through overlying mucosa. One was 16 cm., another 48 cm. One of Zenker's cases of special interest was an aberrant pancreas with a finger-shaped diverticulum of 5.5 cm. length, 44 cm. from the ileocecal valve. In these cases the coats of the accessory pancreas varied; i. e., microscopic examination showed tissue resembling pancreas, save that the interlobular tissue was frequently more abundant. Zenker diagnosed these tumors as embryonic rudiments. Luttille, in 200 autopsies, found five cases of aberrant pancreas. Wright described one example of the anomaly in which the tissue contained glandular tissue as well as islands of Langerhans. Hilly suggests that part of the primitive growth is separated from the remainder and later acquires an independent duct. In the *Index Medicus* of 1910, report of only one case was found—Nazari's case of aberrant pancreas in Meckel's diverticulum.

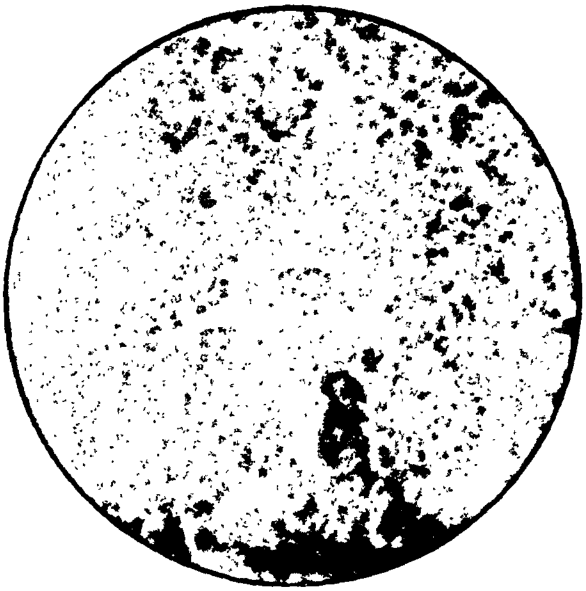

Fig. 3.—Same as Figure 2. High-power lens. Shows cellular structure of the organ.

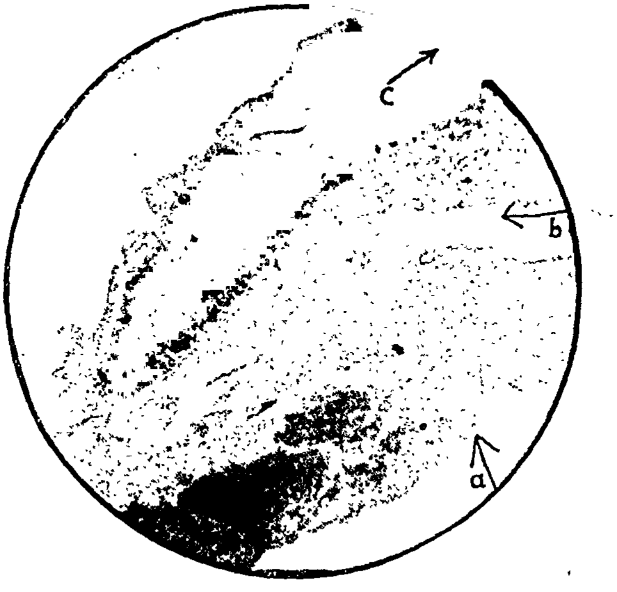

Fig. 4.—Section of intestine attached to the tumor; a, peritoneal surface of small intestine, showing longitudinal and circular muscular coats of intestine beneath; b, submucous coat with its bloodvessels and lymphatics; c, mucous membrane of small intestine.

REPORT OF CASE

History.—A well-developed, robust-looking Italian, male, aged 34, was brought into the hospital with a penetrating bullet wound of the abdomen. At autopsy all organs were found normal except the peritoneum, which showed extensive peritonitis. The intestines were matted together owing to the same condition. In the intestine 75 cm. from the pylorus two perforations were found, i. e., wound of entrance and wound of exit. About 15 cm. from the sigmoid flexure in the descending colon another perforation was seen. About 30 cm. from the pylorus a flat tumor mass was found in the intestinal wall, on its free border, opposite the mesentery. It was yellowish-gray, about the size of a quarter, markedly defined from the surrounding tissue, and slightly protruding into the lumen of the bowel. The tumor and part of the intestine for about 7 cm. on each side of it were removed and sent to the College of Physicians and Surgeons, Baltimore, for microscopic examination. Dr. William Royal Stokes reported the tumor to be an accessory pancreas, or, as some may call it, "aberrant or supernumerary pancreas." On section the organ had the same yellowish gray color as the pancreas. Sections of it showed that it was enclosed on one side by peritoneum and some muscular tissue, and on the other side by the submucous coat and the mucous membrane.

Dr. H. W. Stoner made the photomicrographs here shown (Figs. 1-4).

To the embryologist, physiologist, and pathologist this condition must surely be of some interest as to its correlation with the true pancreas in health and disease. Interesting queries can be evolved from such an anomaly, as, for instance, whether the presence of such a tumor could prevent diabetes in a patient in whom the islands of Langerhans of the true pancreas were affected. Or whether in a diseased condition of the pancreas, would the accessory pancreas undergo sympathetic degenerative changes or hypertrophy and take up the function of the true pancreas?

A PLASTER SUPPORT FOR GASTROPTOSIS

S. D. DICE, M.D.
SARANAC LAKE, N. Y.

I have employed for some time with good results, a useful method of securing abdominal support, with zinc oxid adhesive plaster on moleskin. It is adapted to cases of gastroptosis and enteroptosis requiring some mechanical support in the various wasting diseases, especially chronic tuberculosis, in which digestive disturbances are so common and so important to correct.

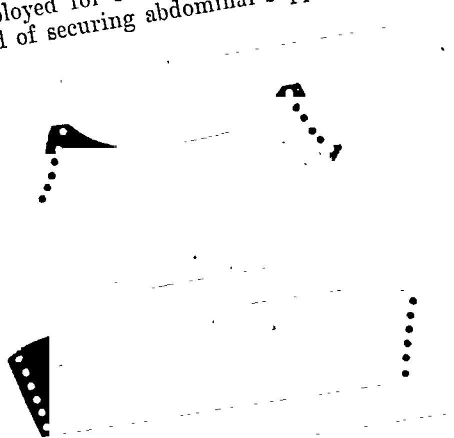

Fig. 1.—Pattern for plaster support for gastroptosis.

A patient in bed will often experience relief and benefit from the constant wearing of a light plaster support of the abdomen, although it is generally assumed, on theoretical grounds, that the sagging viscera require no support at such times. Elastic belts for abdominal support are often not comfortable or effective in the lean individual with a flat abdomen, even with an extra pad inserted under the belt, and holes cut in the elastic to ease up the pressure over the bony prominences at the sides. The plan herewith presented consists of a plaster pattern, with eyelets at the sides for lacing, as now generally used in surgical dressings, when it is desired to avoid a change of plaster at each dressing.

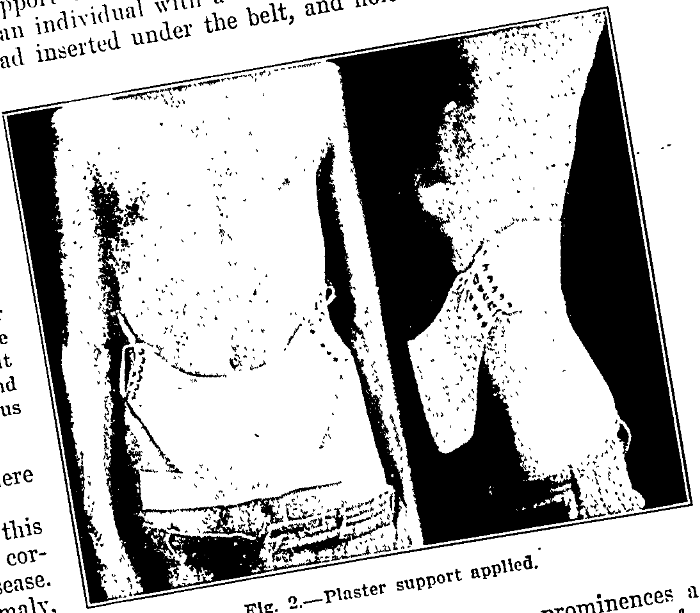

Fig. 2.—Plaster support applied.

The shape and size of the plaster apron will vary, of course, with each individual. The general outline is shown in Figure 1.

The plaster should extend from the umbilicus to the symphysis pubis, and in order to include the side tongues in the same piece with the apron, the 7-inch wide plaster will be necessary. (Fig. 2.)

The strap for the back should be 3½ inches wide, cut straight, or slightly curved toward the ends; the length must be about 3 inches shorter than the actual measurement, leaving the space of 1½ inches on each side, for the uplift traction on apron ends and lacing. (Fig. 2.)

The edge of the plaster along which the holes are punched for eyelets should be faced underneath with an extra narrow plaster strip, so as to make a double thickness to give the eyelets a better staying grip. Less traction on the plaster will be required, when it is laced up, if the patient assumes the recumbent position, which will relax the abdominal muscles and allow the viscera to lie in a more natural position.

The advantages claimed for this pattern and lacing are evident:

1. Quick relief is afforded by unlacing, when the abdomen distends with gas.
2. The single thickness of plaster over the abdomen obviates the necessity for an overlapped edge which often causes a sore ridge on the skin, in the methods requiring a three- or four-piece pattern.
3. There is a small economy of plaster over other methods.

4. It permits easy removal for a tub bath, and a reapplication of the same plaster by the patient, provided (a) that the skin is cleansed of bits of adhesive residue, with turpentine, which should be used before wetting the skin, and removed at once with soap and hot water to avoid irritation; and (b) that the abdomen is shaved clean of new hair growth after every bath.

When the plaster is reapplied to the skin, if it does not adhere readily with the aid of a hot-water bag over the abdomen, then a strip of fresh plaster may be strapped across the lower abdomen temporarily (as shown in Fig. 2 on the left) allowing one-half to lap over lower edge of apron, the other half to extend lower on the skin. After fixation is assured, this temporary strip may be taken off.

The insertion of the eyelets at the sides will be found convenient when the abdomen has been strapped with plaster according to Dr. Rose's method or any other.

104 Park Avenue.

A TABLE FOR EYE, EAR, NOSE AND THROAT WORK

L. W. DEAN, M.D.
IOWA CITY, IA.

This table was designed with the view of securing one that would serve equally well for a cataract operation, brain surgery, mastoid operations, throat work, laryngotomy or bronchoscopy. The table has now been in use for one year and has filled the requirements for this work. The table can be raised to a height of 41 inches and lowered to 31 inches. This allows the operator to work standing or sitting. The table may be tilted to any desired position. This can be done very rapidly if difficulty with anesthesia or other conditions indicate the need for a change of position.

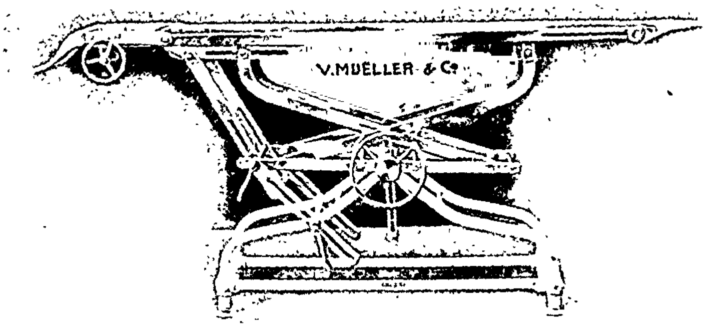

Fig. 1.—A table for eye, ear, nose and throat work, shown with the top of table horizontal.

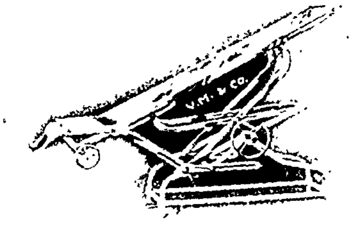

Fig. 2.—View of table with head lowered.

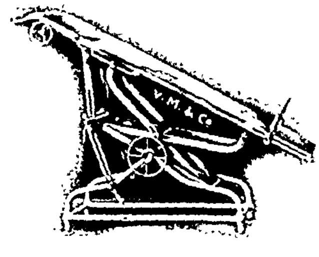

Fig. 3.—View of table with head elevated.

The head-piece of the table may be elevated to any desired position. This advantage, together with the tilting of the table, greatly diminishes the work in bronchoscopy and laryngectomy. In bronchoscopy it is not necessary to have an exceedingly well-trained assistant to hold the head.

The table is firm in every position and there is but slight opportunity for wear.

MITRAL STENOSIS OF TRAUMATIC ORIGIN *

DAVID RIESMAN, M.D.
PHILADELPHIA

History.—N. H., an able-bodied married man of thirty-five, a musician by profession, was returning from a playing engagement one morning at 4 o'clock in the month of August, 1910. Suddenly, when about three squares from home he was set on by foot-pads. Terror-stricken, he ran as fast as his legs would carry him, grasping tightly in one hand his violin and in the other a heavy box containing his music. He arrived at his home utterly spent and exhausted, and with an intense feeling of choking and suffocation. For half an hour he had to stand up and struggle for breath. Gradually the sense of suffocation lessened, its place being taken by a distressing palpitation. There was no real pain. Later in the day the patient consulted a physician, who told him there was nothing serious the matter with him, and that he would soon be well again. By the following day, the palpitation had ceased. Two or three months later it returned, and has troubled the patient intermittently ever since. It caused him to consult me March 21, 1911.

Examination.—I found a presystolic thrill in the apex region, a loud churning presystolic mitral murmur, accentuation of the second pulmonic sound, and, on a later examination, a doubling of the second sound at the base of the heart.

The man's history is entirely negative; aside from an attack of lumbago some years ago, he remembers no illness whatsoever. His mother died at 55 years of age, of a cause unknown to him. His father is still living. Prior to the episode that I have related, he was in every sense, so far as he knew, sound and well.

How shall we interpret this case? I am well aware of the difficulty of proving a given case of heart disease to be the result of trauma. A cursory glance over the literature is not particularly informing, except that it leaves little room for doubt as to the fact that injury and strain can produce functional and muscular disease of the heart. With respect to endocardial, particularly valvular, lesions, the testimony is more questionable. In accidents such as crushes or severe contusions, hemorrhages and tears have been found in the valvular and mural endocardium. Bernstein,[1] who, in 1896, collected all the cases of heart disease of traumatic origin recorded—a total of one hundred and twenty-four—found only a few instances of involvement of the valves; none of which corresponds to the case here reported. There are in his list a few cases of mitral stenosis that followed and seemed to be due to violent blows, falls or contusions. A few additional examples are found in Richard Stern's valuable monograph, "Die traumatische Entstehung innerer Krankheiten." Külbs,[2] in a series of cruel and quite unnecessary experiments, succeeded in producing traumatic valvular lesions in dogs—in seventeen out of twenty-three cases. These lesions consisted chiefly in hemorrhages into the tissues of the valve and the adjacent endocardium, with intimations of a reactive inflammation at the margin of the extravasations.

[2] Verhandl. d. deutsch. path. Gesellsch., 1908, xii, 172.

A small number of instances of rupture of valves following violent strain are on record, but it seems that the majority are cases in which the valves had been previously diseased. For reasons easily understood, the aortic valve is in such instances the one usually affected.

In the case I have reported it might be said that the man had had an old endocarditis, and that the violent strain did nothing more than render a diseased but competent heart slightly insufficient. I am aware of the fact that mitral stenosis is the one valvular lesion in which the antecedent history most often defaults. In probably 30 or 40 per cent. of the cases, no cause whatever can be found. In my experience, however, this is true chiefly in the female sex. Indeed, mitral stenosis is very much like chlorosis a disease of young women. In the mitral stenosis of the male sex it is much more common to find a definite etiologic factor in the history.

I believe that the endocardial lesion in my case was the direct consequence of the violent strain on the heart caused by the man's running, heavily laden and at utmost speed, from his pursuers. As to the primary lesion, it was either a rupture of one of the more important chordæ tendineæ or, what is more likely, a hemorrhage into the valvular tissues, with subsequent organization and contraction.

MALTA FEVER IN TEXAS

A REPORT ON THE SERUM REACTION OF ONE HUNDRED TWENTY-EIGHT GOATS IN EDWARDS COUNTY

FOURTH PAPER

ERNEST R. GENTRY, A.B., M.D., and THOMAS L. FERENBAUGH, A.B., M.D.
Lieutenants, Medical Corps, U. S. Army
FORT LEAVENWORTH, KANSAS

In our last communication,[1] we reported a series of agglutination tests on twenty-three goats, eight of which gave a positive reaction with the *Micrococcus melitensis.* In this paper also we reported seven additional cases of Malta fever, three of which had occurred in the Nueces River cañon, in Edwards County, the principal goat raising section of the state. In this county there are approximately 175,000 goats, the individual herds ranging from 500 to 6,000 goats each. These herds consist almost entirely of finely bred Angora goats and are raised for the mohair which they produce. A few Spanish and Maltese goats are still to be found in each herd. The pure bred Angoras were first imported in 1867 from Asia Minor, by Harris. The more recent importations have been almost exclusively from South Africa.

In view of the fact that the disease has been prevalent in this county for many years, especially in the Nueces River cañon, it was thought desirable to make some examination of the goats in that section. The large size of the herds made a thorough examination of each herd impracticable and therefore a certain number of goats were taken from the several herds available. Only female goats were examined, in order to secure milk specimens, but at this season of the year, even if goats were specially selected, very little milk could be secured.

A blood-specimen was obtained in a Wright's capsule from the ear of each goat for the specific agglutination test with *M. melitensis,* all tests being controlled with serum from normal goats. Wherever obtainable, milk specimens were taken from those goats giving a positive agglutination test, centrifugalized and the sediment plated out on glucose-nutrose-litmus-agar plates, in the hope of isolating the organism from the milk.

The following results were secured from the examination of 128 goats in the vicinity of Barksdale, Texas

Herd 1.—About 1,500 goats in herd; 80 goats were examined and 16 gave a positive test with the *M. melitensis* at a dilution of 1 in 20, one giving an agglutination at 1 in 40 in thirty minutes.

Herd 2.—About 500 goats in herd; 12 goats examined; 3 gave good clumping at 1 in 10 dilution, one going also to 1 in 20 in thirty minutes.

Herd 3.—About 1,500 goats in herd; 13 goats examined; 2 gave strong reaction with *M. melitensis* at 1 in 20 dilution in thirty minutes.

Herd 4.—About 1,000 goats in herd; 23 goats examined; 4 gave positive agglutination with *M. melitensis* at 1 in 20 dilution, one going also to 1 in 40 in thirty minutes.

Thus twenty-five out of a total of 128 goats examined (19.4 per cent.) gave a positive agglutination test for *M. melitensis.* Only eight of these had milk and they only in small quantity. Specimens of milk plated out on glucose-nutrose-litmus-agar gave a negative result for *M. melitensis* in each instance.

SUMMARY OF WORK ON MALTA FEVER IN TEXAS

In concluding this series of investigations on the subject of Malta fever in Texas, we have, by blood cultures and agglutinations, established the fact that the disease exists endemically in the goat raising sections of Texas.

We believe that the infecting organism, the *M. melitensis,* is present in the goats of this section, this conclusion being based on the following observation:

1. About 20 per cent. of all goats examined (151) have given a positive agglutination test at 1 in 20 dilution, three going also to 1 in 40 in thirty minutes.
2. All cases reported by us gave a history of association with the goat raising industry and six gave a history of drinking goat milk.
3. A large number of these goats are direct descendants of goats imported from Asia Minor and South Africa where the disease has been proved to exist in goats.[3]

While many of the patients give a history of drinking goat milk, the factor of dust infection must be considered, particularly in the Nueces River cañon, where goat milk is rarely used, but where the houses are surrounded by the dusty bedding-grounds of the goats and the disease is not infrequent. At this time of year (September) conditions are unfavorable for the isolation of *M. melitensis* from goats' milk, and we believe a statistical study of Malta fever in Texas in man and goats, to be of value, should be made in the months of March, April, May and June. This period embraces the kidding season and the time when the goats are in full milk. After this time the goats rapidly become dry. The great majority of cases of Malta fever among the ranchmen are contracted also during this season, when the whole family practically lives with the goat herds, caring for the kids and teaching them to suckle.

CONTROLLING HYDROPHOBIA IN THE HUMAN SUBJECT *

A. M. STIMSON, M.D.
P. A. Surgeon, U. S. Public Health and Marine-Hospital Service
WASHINGTON, D. C.

In considering methods of preventing hydrophobia in man there are certain factors in the rationale of the disease which must be constantly borne in mind. The following are some of the most important of these:

1. Although all mammals are susceptible to rabies, it is perpetuated in nature almost exclusively by the domestic dog, but also to a small extent and in a few localities by wild animals of the dog family and by skunks.
2. Human infection occurs, in the vast preponderance of cases, directly from the rabid dog through bites, and in the remaining minority of cases from animals which in turn have received their infection from dogs.
3. Rabies is an infectious disease, transmissible by bites from infected to healthy animals, and by other methods of inoculation with the specific virus. It never originates spontaneously or as a result of starvation, bad food or water, excitement, fear, or other like causes.
4. Statistics from the most diverse parts of the world show that rabies is not confined to, and not even markedly prevalent during, any particular season of the year. It may flourish at any season.
5. All parts of the world are potentially capable of harboring rabies. Climatic influences do not operate to its extinction.
6. Under the present conditions of communication in the United States, physical barriers are insufficient to prevent the introduction of rabies into any state or territory.
7. Animals may be suffering from rabies, and their saliva may be virulent for some days, before symptoms become sufficiently marked to excite notice.
8. Dogs suffering from furious rabies often have a tendency to run long distances, twenty-five miles or more being reported, often inoculating large numbers of other animals and persons *en route*, and carrying infection into previously rabies-free regions.
9. Animals killed early in the course of rabies may fail to show unmistakable evidence of the disease on microscopic examination, and in this manner the diagnosis may be indefinitely delayed pending the result of inoculation tests.
10. By means of the Pasteur treatment, promptly administered, immunity may be induced in exposed persons to the extent that a mortality of no more than 1 per cent. need be expected from rabid dog bites of the average severity.

Measures based on these premises and designed to prevent rabies in man may be considered under two headings: (A) those directed against the disease in animals; (B) those which provide for the administration of the Pasteur treatment to exposed persons.

A. MEASURES AGAINST THE DISEASE IN ANIMALS

Since the dog is the perpetuator of rabies, eradicative measures must apply first to rabies in dogs. When wild animals perpetuate the disease in a given locality, measures such as are commonly taken against noxious wild animals must be enforced.

Since any section of the country, at any season of the year is potentially capable of harboring rabies, if it be introduced, there are certain measures which should be in operation everywhere and at all seasons of the year. The object of these measures is to reduce the total dog population by eliminating the ownerless uncared-for element and to restrict it to animals owned by masters who have a sense of the value of their animals and of the responsibility of their ownership, and an intelligent interest in their welfare.

I. PERMANENT MEASURES

1. Destruction of ownerless dogs. This implies in cities the maintenance of an official dog-catching force and a pound for the detention and humane destruction of dogs, cats and other animals. In certain rural districts it is feasible to destroy the *animals immediately by shooting.*
2. Legal definition of an ownerless dog as one not provided with a license tag of the current license period.
3. Imposition of a license fee on all dogs which are owned, harbored or cared for by any person, and a license tag issued to be worn by the dog. This tag bears a serial number corresponding to the entry in the official register, which contains the name and address of the owner and a description of the dog. The license fee should be sufficiently large to accomplish a reduction of the number of dogs kept, to impress a sense of value, and should be higher for unspayed females.
4. Rendering dog owners legally responsible for damage inflicted by their dogs. In many sections there seems to be *no redress for such damage save such as is obtained by protracted legal action.* A stray horse peacefully grazing by the roadside would be promptly taken to the pound and held for fines, while there would be no penalty for allowing a dog to run loose annoying or injuring stock and poultry and possibly contracting and transmitting rabies.
5. Education of the dog-owning public in matters relating to the care of dogs as affecting the spread of communicable diseases, especially rabies. This measure is believed to be the most important adjunct or preliminary to the other measures, without which it will be impossible to effect any lasting benefit. The media through which it may be effected are: the press, both public and official; lectures, talks and demonstrations by representatives of the health and veterinary boards; object-lessons in the course of epizootics; the public schools and possibly the pulpit. There is evidence that the average layman does not profit by bulletins and tracts to the desired extent unless he finds them practically and perenially useful, and above all, understandable. They arrive in the waste-basket without even a sojourn in the pigeonhole. For this reason it is urged that information intended to instruct in the methods of preventing rabies be administered in a palatable menstruum, a "Dog-Lover's Handbook" with illustrations, for instance. There should be chapters on the preferred and valuable breeds of dogs, on food and housing, how to build a kennel, what to do for a sick dog when a veterinarian is not immediately available, etc.; but the truths should not be lost sight of, that the majority of dogs are luxuries rather than necessities; that a dog worth having is worth taking good care of; that it is to the personal interest of the dog-owner as well as his duty to avoid the spread of disease by his animals. The essential information concerning rabies should be dealt with in a separate chapter and at appropriate points throughout the bulletin.
6. The organization of a system of securing reliable information concerning the presence of rabies in all portions of the state or territory. The disease should be made reportable, as should also suspected cases, and penalties imposed for non-compliance.
7. State or territorial quarantine against importation of dogs. A measure obviously to be adopted only after a consideration of internal conditions and interstate relations.

II. SPECIAL AND TEMPORARY MEASURES

Under this caption are considered those measures which are to be applied with discrimination, *pro re nata.* They are best administered by a central authority free from local affiliations and prejudices, but well informed through its agents on local conditions. Their selection, duration and area of application are to be decided on after consideration of the specific case.

1. Muzzling.—This measure should be applied whenever an outbreak of rabies occurs, and maintained sufficiently long after the cessation of new cases to warrant a feeling of security that the outbreak has been eradicated and is not merely in abeyance. The only justification for short periods of muzzling is the uncertain one that they may be applied with less opposition and greater thoroughness. It would appear that the greater the area included in an ordinance, the less time it will be necessary to maintain it. Basing the necessary period for eradication on the possible incubation period in dogs, a minimum period of six months and a maximum of one year would be necessitated. The area in which an ordinance is operative should exceed that of the known extent of the outbreak in order to surround it with a safety zone. Muzzling ordinances for certain months or seasons of the year, when based on a supposed seasonal prevalence, are in the face of the facts, illogical. Ordinances should prescribe that muzzles be constructed of metal, should prevent biting, should be humane, and should be fitted to the animal.

---

* Read in the Section on Preventive Medicine and Public Health of the American Medical Association, at the Sixty-Second Annual Session, held at Los Angeles, June, 1911.

2. *Restraint of Dogs.*—This measure may be employed as an alternative or as an adjuvant to muzzling. If well enforced it should be effectual in preventing the spread of infection, but it does not relieve the owner of an already infected dog from the danger of infection. It places the responsibility for an infection in the family or personnel of a household, on the owner of the dog, but does not remove the possibility of infection. Restraint means fastening up with a chain (not a rope), or confinement within an enclosure from which the animal cannot escape. Since it is the custom of unscrupulous persons to liberate their dogs for exercise after nightfall in violation of an ordinance of restraint, special provision against this infraction is necessary. The dogs may be exercised while muzzled, and preferably for their own protection led in leash. Leading in leash unmuzzled is so easy of evasion that it is not to be recommended. The period and area of restraint ordinances are governed by the same considerations as in the case of muzzling.

3. *Disposition of Supposedly Infected Animals.*—Animals which have been subjected to bites by other animals which have rabies or in which there is good ground for suspecting it should be immediately killed or quarantined. In the case of dogs and cats it is wisest that they be destroyed. Live stock and other animals of especial value may, at the discretion of the authorities, be subjected to isolation or quarantine under official supervision, for a period of not less than six months, the expenses being borne by the owner.

4. *Disinfection.*—The necessity for disinfection of objects soiled by the saliva and other discharges of rabid animals does not appear to be pressing, but since a possibility of danger from such objects is conceivable, and a chance of infection arising in this manner would bring great discredit on the authorities, it is advisable to provide for disinfection. This may be carried out by burning the litter of stables, kennels, etc., subjecting more valuable objects to the action of boiling water, steam or chemical disinfectants, and washing down walls and floors which may have been soiled with disinfectant solutions, or a fresh coat of whitewash. The commercial use of any part, including the hide, of an animal killed for rabies must be prohibited unless such parts have previously been rendered innocuous to the satisfaction of the authorities. Proper disposal of carcasses must be enjoined.

5. *Compulsory Notification of New Cases of Rabies and Animals Bitten.*—By the enforcement of this rule new foci of infection may early be recognized. When temporary measures are to be applied in a territory, the public must be informed through the newspapers, by special printed announcements, by verbal notification by a representative of the authorities, or by conspicuous posters. This notification should comprise a statement of the local prevalence of the disease and the danger to human and animal life involved, a statement of the exact area and time period of application, the provisions of the ordinance, a quotation of the authority and the penalties for non-compliance.

A supplementary note as to sources of information and as to the examination of suspected material would be in the direction of increased efficiency.

6. *Local Quarantine.*—The central office should have authority to impose a quarantine on infected towns, cities, counties, etc., making it illegal for any person to remove dogs or other animals capable of transmitting rabies from the infected district except under official certificate that they are free from rabies infection.

B. *PASTEUR TREATMENT*

There are now some twenty institutions in the United States where the virus for the Pasteur treatment or one of its modifications is prepared and administered. Some are under private management and others are under state or municipal auspices. The Public Health and Marine-Hospital Service through the Hygienic Laboratory, Washington, D. C., is prepared to furnish gratis on request, glycerinated virus to state health authorities having the necessary laboratory facilities.

Because of the saving of time and expense permitted by it, the treatment of patients at or near their homes is preferable to treatment at a central station which may be far distant. This has been made practicable by the use of glycerinated virus, which is sufficiently stable to permit of shipment by mail or express. It has been used in two forms; that of an emulsion containing glycerin as a preservative, and in the form of the cord itself cut into pieces suitable for a dose, and bottled in glycerin. The latter would appear to be the more stable form but necessitates emulsification under aseptic conditions at the place where it is used.

The preparation of the virus necessitates the services of a bacteriologist with special training and experience in connection with rabies, and such skilled or unskilled assistants as may be needed, according to the amount of work. The equipment consists of a plant for maintaining an adequate supply of rabbits, rooms for the preparation and administration of the virus, two incubators, an ice-chest or refrigerator, and various instruments, glassware, and chemicals. The examination of suspected material for diagnosis may conveniently be included in the duties of the director. The ethics of a state's supplying the virus to needy persons would appear to be the same as in the case of diphtheria antitoxin.

THE MECHANISM FOR CARRYING OUT THE FOREGOING MEASURES

Each state and territory should vest authority for the control of rabies in a central office. Such powers are now commonly entrusted to the state board of health or the state agricultural department or corresponding bodies, or divided as regards certain functions or districts (municipal or rural) between those agencies concerned with human health, and those pertaining to the welfare of domestic animals. The most effective work in the control of the disease will be secured from that agency which has or can develop the best organization of its personnel, and which has competent representatives in the greatest number of localities throughout the jurisdiction. The centralization of authority is necessary for the coordination of the work and the securing of uniformity. Otherwise certain delinquent communities will habitually harbor rabies, to the detriment and discouragement of the neighbors.

The functions of the central office will be as follows:

1. To collect information regarding the prevalence and distribution of rabies in the lower animals and in man.
2. To publish for public distribution information concerning rabies.
3. To investigate reported cases and epizootics.
4. To maintain permanent and apply temporary measures of control or to supervise the carrying out of these measures by local authorities.
5. To cooperate with corresponding authorities in contiguous states.

6. To provide a laboratory for the examination of suspected material.
7. To provide for the administration of preventive inoculations to exposed persons.

Each outbreak of rabies will naturally present peculiar features calling for the exercise of judgment as to the methods to be employed, but for the sake of illustration of the workings of the central office, a hypothetical outbreak will be assumed and described. It is assumed that a central office, say the state board of health, is responsible and authorized for the control of rabies, and that it has put in force the permanent measures previously described; that is, it has instructed the local health officers to report suspected cases, has attempted to reduce the ownerless dog population, has placed information concerning rabies at the disposal of the dog-owning public, and has enforced the license fee. Since conditions in large cities will be attended to by the municipal authorities under the supervision of the state authority, a rural outbreak will be supposed.

A health officer in a small town reports that a dog coming from a neighboring village has entered the town exhibiting the symptoms of rabies, has bitten other dogs and stock and several persons; that the dog has subsequently died and that the head of the animal is being sent for examination. The state office will subject the dog's head to laboratory examination, and in the event of a positive result, will order such temporary measures as in its judgment seem indicated, advising the bitten persons to take preventive inoculations and informing them how this may be arranged. It will also communicate with its representatives in the towns adjacent to the infection, and in case the outbreak is on or near the state line, with the corresponding office in the contiguous state. In case the local representative is obviously unable to cope with the situation as it develops, a special agent must be sent to take charge.

A plan which is giving promising results in at least one state where the control of rabies is entrusted to the veterinary authorities, includes the making of a temporary agent of the local veterinarian, with per diem compensation. This agent is charged with the duty of reporting on local conditions, and carrying out such measures as are prescribed. When necessary, a special agent is sent from headquarters to destroy stray unmuzzled dogs, which he accomplishes with great thoroughness with a shotgun. It is not unusual for communities to request voluntarily that this agent be sent to clean out the stray dogs from the town, even when there is no rabies present. Unfortunately quite the opposite attitude is to be expected in many parts of our country.

DIFFICULTIES AND CAUSES OF UNSUCCESS

Aside from inadequacies in the central administration arising from lack of legal authority, lack of funds, the pressure of more important duties, or even from indifference or incompetence, there are other obstacles which render the eradication of rabies a matter of great difficulty, and this in spite of the fact that the perpetuation of the disease is due to one isolated fact, namely, that dogs will bite, and that its prevention is in essence comprised in a single measure, the prevention of their biting. The mental attitude of the average dog-owner is the greatest obstacle to success. Ignorance is the chief factor determining this attitude, and it should be a special aim of the authorities to dispel this ignorance. A second factor is indolence or indifference, for which salutary stimulation is indicated. A third factor is personal interest of the dog-owner to comply with and support measures against rabies.

A second great obstacle has arisen from a lack of that uniformity and correlation in the methods employed in adjoining territories, which can only be secured by an impartial central authority for each state and by interstate cooperation. Thus, no matter how conscientiously and effectually one community may have dealt with its rabies problem, the constant reintroduction of infection from a dilatory neighbor is sure in the end to discourage and demoralize. In this connection it is instructive to recall that in England it was only after the antirabies operations were entrusted to a central authority that a permanent amelioration and finally complete eradication was effected.

ABSTRACT OF DISCUSSION

Dr. Calvin S. White, Portland, Ore.: We have during the last year had rabies for the first time in the northwestern part of our state, where it is very sparsely settled and where the sheep industry is the only one. The sheep men cannot afford to destroy their dogs; and they tell me that the dog that is muzzled will not work. We have had it among the coyotes, and several that have been sent to our laboratory have shown the Negri bodies in large quantities. There have been only two cases that I know of in which human beings have been bitten, one by a coyote and the other by a dog; in both animals we were able to establish the presence of the Negri bodies; and we used Pasteur treatment on both the patients. How are we going to disinfect the saliva of a dog? The infection is in the whole of the animals that we examined: not only in the saliva but in the teeth and in the humors of the eye, and it seems to me it would be out of the question to do it. I would like, also, to know how a certificate could be given that a dog was free from rabies when we found that the period of incubation varied so before the disease developed. I don't see how any one's certificate could possibly be of any value, if the dog had ever been inoculated.

Dr. Norman Bridge: I don't know any way except keeping the animals long enough in quarantine to be sure. I presume that would cover it.

A CASE OF ANGIOKERATOMA

E. H. TROWBRIDGE, M.D.
Assistant Physician State Hospital No. 2
ST. JOSEPH, MO.

The article on angiokeratoma by Dr. Richard L. Sutton[1] suggests the report of the following case.

History.—Patient, P. M. K., a man aged 61, complains of slight ache of testicles. He has followed occupation of engineer previous to his admittance to hospital, and has always enjoyed excellent health. The cutaneous history of the family is negative. The patient's circulation has been good till recently when symptoms of heart involvement developed. There is a very vague history of chilblains. The patient was hit by a baseball in left testicle, twenty-six years ago, immediate swelling of testicle following, however, with very little discomfort at the time. Swelling has persisted since, fluctuating in size from time to time but unaccompanied with any noticeable symptoms except a slight ache. The superficial capillaries have been prominent for an indefinite period of time, the patient first noticing the skin lesion about two years ago. The tumors increased in numbers from time to time and the patient has noticed that a few of them have slowly disappeared.

Examination.—The patient is a well-built man, well nourished, 5 feet and 9 inches in height, and weighs 160 pounds. The skin on the hands and feet is smooth and unmarked and there are no lesions on the body. The superficial capillaries of the calf of the leg and lower portion of the abdomen show a tendency toward varicosity. Patient has some edema of the ankles. The scrotum is enlarged on the left side, a chronic hydrocele being present. The integument covering it is roughened and somewhat boggy to the touch. The superficial scrotal veins on left side are dilated and tortuous, and distributed along their course are a goodly number of hard, purplish, smooth, elevated nodules varying from the size of a grain of wheat to that of the head of a pin. On puncture of the larger ones a small drop of serous blood exudes. Some of the nodules are small and in process of development, while others are of a brownish red color and undergoing degeneration. The patient gives a history of chronic venous obstruction preceding the development of the angiokeratoma, the vascular tumors developing as a result of the increased blood-pressure in the superficial capillaries, the walls of which being insufficiently supported, allowing their formation. The chilblain history in this case being so vague, it, as the underlying cause of the vascular lesion may be ruled out.

"SINGER'S NODULE" (CHORDITIS NODOSA) REMOVED BY VOCAL TREATMENT

F. VICTOR LAURENT, M.D.
PITTSBURGH

While these nodes usually occur in singers and public speakers, the following case will show that habitual misuse of the voice by anyone may cause this condition.

While faulty breathing is a factor, the breathing of itself will not develop nodes, the prime factors being overtension of the intrinsic and extrinsic muscles of the larynx which causes the *coup de la glotte* or stroke of the glottis, which, Garcia used to say, is death to the voice.

Kyle says that nodes are usually located near the junction of the anterior and middle thirds of the cords. My experience has proved just the opposite and I generally expect to find them near the junction of the middle and posterior thirds, for the following reason:

When the voice is used properly and the upper register is attempted, the posterior thirds of the cords are closely approximated and not in use and the larynx rises to a higher position, the extrinsic muscles being relaxed. Now, when the pitch of the voice is raised and the larynx is held in the same position as when speaking or singing in the chest or medium register, there is overtension of the extrinsic muscles and the arytenoideus muscle, which causes the cords to vibrate throughout their entire length, and as the posterior thirds are closely approximated, the super-attrition which causes the nodes to develop occurs just a little anterior to this point.

The patient, Mrs. E. J., had not been able to speak above a whisper for six months and had been treated during that time by her family physician with no result. She finally became discouraged and was sent by a friend to Dr. Vansant of Philadelphia who referred her to me. On examining the larynx, I found a nodule on the free border of the left cord near the junction of the middle and posterior thirds. The patient said she had a relative living with her who was very deaf and that during the day she talked very loud to her, pitching her voice higher than usual, and in the evening her voice was always tired and the muscles of the larynx very much fatigued. This is exactly what happens when a singer uses the chest register in singing the higher tones, and the result in this case was the same. The voice gradually became hoarser until it could be used only with great difficulty and there was almost complete aphonia.

On examining the cords during tone-production, I found that when singing the four tones C, B, A and G below the staff, the node did not come in contact with the opposite cord. Taking the patient to the piano, I then instructed her how to speak on these four tones and instructed her how to breathe properly. She was told not to talk at all until she could do so by using only these tones as fundamentals, and, in the meantime, to practice the breathing exercises half a dozen times a day.

In four weeks she had a perfectly normal voice, although pitched considerably lower than formerly. The tired feeling in the throat was also gone because the patient had learned to use her voice in the different registers without keeping the larynx in a fixed position, thus relieving the extrinsic muscles of the heretofore constant strain.

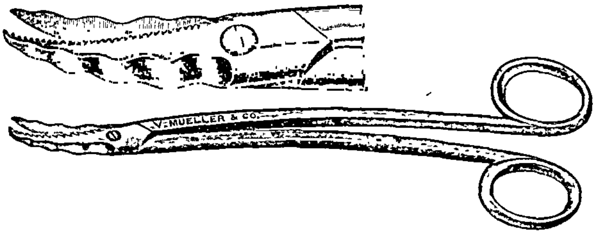
For the removal of the nodule, besides changing the faulty voice production and faulty breathing, external massage of the larynx was practiced and by the end of the third month the node had completely disappeared. For the accompanying hypertrophic laryngitis, inhalations of the compound tincture of benzoin and camphorated tincture of opium were used while the local application of a 2 per cent. solution of silver nitrate was made three times a week.

I wish to emphasize the fact that the main treatment of chorditis nodosa is teaching the patient to use the voice and respiratory apparatus properly. This appears to me a much more satisfactory method than operative measures, as, in the latter case, the node will probably reappear in time, while if the patient has learned to use the voice properly, the cause is removed and there is no danger of recurrence.

NEW TONSIL SCISSORS

WILLIAM S. WINDLE, M.S., M.D.
OSKALOOSA, IOWA

With a view to combining the good points of three instruments in one, for enucleating the faucial tonsil, I have devised the scissors here illustrated. They present these features:



Tonsil scissors with serrated blade.

1. The cutting edge of one blade is serrated and the other smooth; this facilitates the cutting of soft, slippery tissue.
2. The outer edge of each blade is wave-like in outline and beveled to a dull knife edge; this serves as a dissector. By inserting the closed scissors between the tonsil and pillar and then opening them forcibly at four or five points, the tonsil is rapidly exposed and prepared for the snare. The latter may be omitted and the operation completed with the scissors if desirable.
3. The closed scissors may be used as an Allport's or Swan's wave-edge knife for enucleating the tonsil.

Sanitation and the Hookworm.—As Boycott has clearly pointed out, three conditions are necessary for the spread of hookworm disease: (1) a certain degree of temperature, about 68 to 90 F.; (2) a certain degree of moisture; (3) fecal contamination of the ground; and these conditions are found only in tropical and subtropical regions. When the temperature here is suitable for the hatching out and development of the embryo hookworm, the weather is usually too dry; and while the sanitary arrangements, especially in the country districts of New York state, are probably not ideal, they are not to be classed with those in the tropics.—Nichols in *Medical Record.*

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED BY THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION. THEIR ACCEPTANCE HAS BEEN BASED LARGELY ON EVIDENCE SUPPLIED BY THE MANUFACTURER OR HIS AGENT AND IN PART ON INVESTIGATION MADE BY OR UNDER THE DIRECTION OF THE COUNCIL. CRITICISMS AND CORRECTIONS ARE ASKED FOR TO AID IN THE REVISION OF THE MATTER BEFORE PUBLICATION IN THE BOOK "NEW AND NONOFFICIAL REMEDIES."

THE COUNCIL DESIRES PHYSICIANS TO UNDERSTAND THAT THE ACCEPTANCE OF AN ARTICLE DOES NOT NECESSARILY MEAN A RECOMMENDATION, BUT THAT, SO FAR AS KNOWN, IT COMPLIES WITH THE RULES ADOPTED BY THE COUNCIL.

W. A. PUCKNER, SECRETARY.

ADALIN.—Adalin, $C(C_2H_5)_2Br.CONH.CONH_2 = C_7H_{13}O_2N_2Br$, is brom-diethyl-acetylcarbamide.

It is prepared by the action on urea of brom-diethyl-acetyl bromide, obtained by the action of bromine on diethylacetic acid anhydride.

Adalin is an almost colorless and odorless crystalline powder, with a melting point of 116° C. (240.8° F.), which dissolves readily in alcohol as well as in the other ordinary organic solvents. It is difficultly soluble in water.

Actions and Uses.—Adalin is said to be an efficient and prompt sedative, reducing excitement and promoting sleep in conditions in which a powerful hypnotic is not required. In therapeutic doses it is said not to exert any unfavorable influence on the respiration or heart action. The sleep produced is said to be restful, dreamless and exceptionally free from unpleasant by-effects and sequelæ.

Adalin is said to be useful as a sedative and mild hypnotic in neurasthenia, hysteria, cardiac neuroses with tachycardia, chorea, mental disorders with moderate excitement, and insomnia due to various internal diseases, etc.

Dosage.—As a sedative 0.3 to 0.6 Gm. (5 to 10 grains), given in cold water, repeated three or four times daily it necessary; as an hypnotic 0.6 to 1.0 Gm. (10 to 15 grains), followed by a drink of hot, sweetened water or weak tea.

Manufactured by the Farbenfabriken vorm. Friedr. Bayer & Co., Elberfeld, Germany (Farbenfabriken of Elberfeld Co., New York). U. S. patent No. 983,425 (Feb. 7, 1911; expires 1925). U. S. trademark No. 81,136.

Adalin Tablets, 5 grains.—Each tablet contains adalin 0.33 Gm. (5 grains).

BULGARA TABLETS.—Tablets containing a practically pure culture of bacillus bulgaricus.

Bulgara Tablets consist of the slowly dried cultures mixed with milk sugar and starch, each tablet weighing 5 grains and containing a sufficient number of virile organisms to effect the souring of a pint of sterile milk in less than 20 hours.

Actions and Uses.—The bacilli contained in bulgara tablets give rise to the production of considerable quantities of lactic acid which tends to restrain the growth of putrefactive organisms. They are said to be useful in diseases of the alimentary tract and in such general diseases as are believed to depend on putrefaction in the intestines.

Dosage.—One or two tablets before or after meals. The diet should contain a sufficiency of sugar.

Bulgara Tablets are marketed in tubes, each containing fifty tablets, with an expiring date stamped on the label.

Manufactured by Hynson, Westcott & Co., Baltimore, Md. Not patented or trademarked.

FERRO-SAJODIN.—Basic, ferric iodobehenate. Ferro-sajodin is basic, ferric iodobehenate having the approximate formula $(C_{21}H_{42}ICOO)_2(OH)Fe = C_{44}H_{85}O_5I_2Fe$, and containing about 5.7 per cent. of iron and about 25 per cent. of iodine.

Ferro-sajodin is produced by the interaction of iodobehenates and iron salts.

It is a reddish-brown powder, unctuous to the touch. It is insoluble in water; soluble in chloroform and ether. On heating it melts to a brownish-black liquid which emits an abundance of iodine vapors.

Actions and Uses.—It has the action of iodides and of iron. It is claimed to be more stable and palatable than ferrous iodide and not to injure the teeth or disturb the gastro-intestinal tract and is said to be free from a constipating tendency. It is claimed that it is easily absorbed but slowly eliminated, assuring a more prolonged effect.

It is indicated in conditions in which iron and iodine are employed, such as anemia, rickets, syphilis, chronic bronchitis, arteriosclerosis with anemia, etc.

Manufactured by the Farbenfabriken vorm. Friedr. Bayer & Co., Elberfeld, Germany, and Farbwerke vorm. Meister, Lucius and Brüning, Hoechst a. M., Germany. (Farbenfabriken of Elberfeld Co., New York.) Not patented or trademarked. Sold in the form of tablets only, see below.

Tablets of Ferro-Sajodin, 8 grains.—Each tablet contains ferro-sajodin 0.5 Gm. (8 grains).

Dosage.—1 or 2 tablets, three times daily; for children ½ to 1 tablet, three times daily.

Tablets should be thoroughly chewed before swallowing, or in the case of small children crushed before administration.

NON-PROPRIETARY BRANDS OF ACCEPTED ARTICLES

Having been found to comply with the standards adopted, the Council voted that the following brands of accepted articles be listed:

Scarlet R. Medicinal Biebrich, Merck.—

Manufactured by E. Merck, Darmstadt, Germany (Merck & Co., New York).

Not patented or trademarked.

Sodium Perborate, R. & H.—

Manufactured by the Roessler & Hasslacher Chemical Co., New York.

Not patented or trademarked.

PHARMACEUTICAL PREPARATIONS ACCEPTED FOR N. N. R.

The following dosage form of an accepted proprietary article has been accepted for N. N. R.

Supracapsulin Ointment.—An ointment containing 0.1 per cent. of Supracapsulin in a base of hydrous wool fat.

Therapeutics

ASPHYXIA

(Concluded from page 1057)

ASPHYXIA FROM SUBMERSION: DROWNING

Most individuals who become asphyxiated from submersion in water or from drowning are dead when they are taken out of the water, and all efforts to restore them to life are futile. This is especially the case if complete submersion has lasted four or five minutes. The occasional instances of the successful treatment of this form of asphyxia, however, make it incumbent on the physician to be thoroughly informed as to the best methods to employ in the treatment of these cases, and to be prepared to carry them out if he happens to be near by when the patient is taken out of the water.

In the first place, the water must be expelled, so far as possible, from the respiratory passages. Probably there is no better way of doing this than by inverting the patient by taking hold of his feet and raising them up and letting his head hang down. This is a simple maneuver, provided the bystanders have strength enough to carry it out. Rolling the patient on a barrel is a crude and harsh substitute. Having removed the water as far as possible from the chest, the next thing to do is to perform artificial respiration. There are a number of methods of doing this.

The so-called method of Marshall Hall was first described in 1858, and consists in rolling the patient alternately from the lateral to the prone position and pressing on the back between the shoulder blades when he is in the latter position. This has the advantage that the tongue does not fall back into the throat and so obstruct the larynx, and the water and mucus are able to flow out of the mouth.

The following year the so-called Sylvester method was described. This consists in allowing the patient to lie on his back with his shoulders raised and his head hanging low. The operator then takes hold of the arms of the patient above the elbows and draws them gently away from his body until they arrive at a point above his head. This raises the ribs and increases the capacity of the chest. The arms then are carried down by the side and the elbows flexed and pressed against the lower part of the chest, thus diminishing the capacity of the chest and driving the air out. In this method the tongue is likely to fall back into the throat and interfere with respiration unless some one grasps it and pulls it forward.

In 1868, Dr. B. Howard, of New York, described a method of treating these cases which consists in laying the patient on his back while the physician kneels over the lower part of the body and presses on the lower part of the chest so as to diminish its capacity. He then relaxes the pressure, and the natural elasticity of the chest increases the air capacity. In this method also the tongue is liable to fall backward, and must be drawn forward. It is objected that in elderly patients the ribs are brittle and may be fractured, and that the liver is congested and may be ruptured.

Finally it remains to describe the method known as that of Professor E. A. Schäfer, professor of physiology in the University of Edinburgh. He recommends that the patient be placed in the prone position. The physician being astride the patient, the open hands are placed on either side of the lower ribs and firm, but not violent pressure is exerted. This may be done by allowing the weight of the body to come on the arms. After this pressure has been exerted for three seconds the body may be brought upward and the pressure relaxed. This should be repeated at intervals of five seconds, or twelve times in a minute.

Schäfer made investigations with a view to comparing the utility of the various methods of artificial respiration. He found that in natural respiration the air exchanged in a minute by a person breathing thirteen times a minute was 5,850 c.c. The amount of tidal air at each breath therefore would be 450 c.c. Employing the Sylvester method, the amount of air exchanged in a minute was 2,280 c.c., showing the tidal air of each breath to be only 175 c.c. With the Marshall Hall method the exchange of air was 3,300 c.c., with a tidal air volume of 254 c.c. With the Howard method the exchange per minute is 4,030 c.c. and the tidal air volume 310 c.c. With his own method he was able to pump through the lungs per minute 6,760 c.c., showing a tidal air volume of 520 c.c. He therefore believes that this is the most efficient method of performing artificial respiration. He states that the advantages are: "1, it is fully efficient; 2, it can be performed without fatigue by a single individual; 3, it is simple and easily learned; and 4, it allows the tongue to fall forward, and the mucus and water to escape from the mouth, so that the tendency of these to block the passage of air, which is inherent to the supine position, is altogether obviated."

This subject was discussed at considerable length by Professor Schäfer in THE JOURNAL, Sept. 5, 1908, page 801.

In treating these cases it is important to preserve so far as possible the warmth of the patient. Woolen blankets should be obtained, and, after the surface of the body has been thoroughly dried, wrapped about him. While artificial respiration is being employed, friction of the surface of the body, especially from the extremities toward the center, should be carefully but not roughly done. It is recommended that artificial respiration should be continued for from one to two hours, but it seems that there is very little use in continuing efforts to restore respiration after the action of the heart has ceased. As long as the action of the heart continues, the artificial respiration should be continued, regularly and systematically.

Some hospitals are establishing apparatus for promoting and compelling respiration in patients who have from ether, chloroform or other acute causes, ceased to breathe.

PRESCRIPTION-WRITING

While not strictly therapeutics, correct prescription-writing is such a close corollary to good therapeutics that it seems pertinent to introduce it in this department, and although some of the material which will appear in this and a few subsequent issues seems elementary, it is hoped that the physician who cares to read it will pardon such detail in order that the subject may be presented entire.

CHAPTER I.—INTRODUCTION

Therapeutics in its broadest sense is the ultimate aim of the science and practice of medicine. It includes not only drug therapy, to which its definition is so often erroneously limited, but also everything that has to do with the treatment of the disease, the management of the patient, of his convalescence, of his permanent return to health, and of the prevention of disease attacking the well. In other words, it is the practical application of all of the knowledge acquired by study, research and practice to the understanding and treatment of disease.

Besides aiming to suggest orthodox and valuable methods of treating some of the common diseases, it is the object of this department also to aid in the proper writing of prescriptions, as nothing more denotes an educated and up-to-date practitioner than his ability to write simple and correct prescriptions.

That it is utterly unimportant to the patient what name the physician gives to his disease or condition is self-evident. He comes to be cured, or at least to have his troublesome symptoms ameliorated, and while a diagnosis is positively essential for perfect therapy, fortunately or unfortunately, it is not always necessary for an amelioration of his symptoms or even, sometimes, for his cure. Consequently, many times the patient is as successfully treated, from his point of view, by a quack or an ignorant practitioner as he is by a scientific physician. It is also unfortunately true that many a scientific physician, owing to his medical training and to some of the best text-books on the practice of medicine, delays the amelioration of the patient's symptoms until slow laboratory processes have made a definite, positive diagnosis. Such diagnosis having been made, he is content to treat the cause of the condition, forgetting even the pain the patient is suffering, and thus his patient is often driven to quackery or dogmas or "patent medicines," and often improves from such treatment.

It should be taught not only in the therapeutic departments, but in the internal medicine departments of every medical school, and no text-book on practice should be considered complete unless it teaches that the uncomfortable, disagreeable and non-eliminative symptoms of a disease must be attended to and therapeutically managed while the disease itself is being scientifically combated. Every clinician well knows that it is the consultant only who can ignore the treatment of troublesome symptoms. All successful quackeries succeed because of their ability to relieve symptoms or to cause such mental suggestion as will relieve overtaxed minds, and many a loyal patient is driven to employ quackery by scientific neglect.

The administration of drugs is only a small part of the management of disease, and the management of disease is the highest pinnacle of the medical curriculum. It presupposes all the physiologic, chemical, anatomic, pathologic, bacteriologic and pharmacologic knowledge that can be obtained. This knowledge is then brought to bear on the management of the disease, which means necessary hygienic changes, perhaps a change of climate, an arrangement of the food and drink, physical treatment if indicated, such mental treatment as is advisable, such medicinal treatment as is needed, and necessary operative procedures, and, altogether, this is therapeutics. The subject of therapeutics is, then, the broadest and the hardest one for the medical student to grasp, and it is safe to say that the young graduate in medicine, even after a hospital course, is less prepared in the bedside and office management of disease than in any other branch of his art.

A proper understanding of and proper teaching of the ability of the mind to overcome many nervous disorders, to prevent the misinterpretation of, and the exaggeration of, slight physical disturbances should be encouraged. Psychotherapeutic instruction should be given in every medical school, and hospitals should have psychotherapeutic wards.

As scientific practitioners are just passing out of the age of drug nihilism and a belief that because a disease cannot be cured by specifics the patient should receive no treatment, we find the necessity for a better understanding of pharmacology. Just as a mental therapist will be cured of absurd prognoses and beliefs by the study of pathology, so does a thorough knowledge of the pharmacologic action of drugs prevent a doubt of their efficiency. Hence it is absolutely necessary for every medical school to furnish laboratory pharmacologic instruction. The medical graduate after such a course will demand pure, active drugs, and will use them rationally.

It is time to repudiate the assertion that Nature is a good physician or a good surgeon. It is not necessary to controvert the belief of ancient, medieval and modern medicine, as evidenced by the various Greek, Arabian, Latin, German and English terms, that the human organism is able to combat poisons and infections and to heal lesions. But we have now come to the time when it should be recognized that we not only must not obstruct in the human body the processes of eradication of an infection which natural metabolism has established; but that it is just as futile and just as absurd not to aid in combating an acute or chronic disease with the proper drugs, all correct physical and hygienic methods having been instituted, as it is to allow pus to burrow and cause serious consequences instead of properly evacuating it. In other words, natural processes are fighting just as much to perpetuate the condition or disease or infection that is abnormal to the part, as are the natural processes of the human body endeavoring to eradicate these foreigners who have invaded their stronghold. Who for one moment can think that the cancer cell is not attending to its natural function of multiplying and eating into healthy tissue, and who would allow to-day such a process to go untreated? Who would allow the diphtheria germ and its toxins to have full sway without the use of its opponent, antitoxin? It is just as absurd to declare that pneumonia and typhoid fever need no medication as it would be to declare that diphtheria needs no antitoxin and no antiseptic gargles.

The proper use of drugs that have physiologic activities being acknowledged helpful and often curative agents, it is self-evident that we expect and demand a standard of strength and purity of such drugs as laboratory and clinical determinations have proved valuable. Consequently, we await the ninth revision of the United States Pharmacopeia with hope and faith that it will furnish the standards of useful drugs, and trust that it will not officialize and attempt to standardize drugs of no therapeutic value and of no pharmacal necessity. A standard book that contains many useless articles and standardizes many common substances insults its articles of value and loses them in a fog of uselessness.

While simplicity in prescription-writing is advisable, it cannot be gainsaid that the art of combining drugs or of rendering a drug less disagreeable should be taught in the medical schools. Even with this laudable object in view, however, it is not justifiable for a physician so to belittle his profession and forget rationality in his treatment of a patient, to say nothing of the enormous graft which he hands the proprietary firms from the pockets of his patients, by ordering proprietary mixtures. The physician who orders such preparations does not realize the positive harm he often does his patients, in some instances almost amounting to criminal negligence. No one deems it reputable, or scientific, or just to patients to prescribe preparations the ingredients of which he does not know. This is little less than malpractice. The patient pays for our opinion. If we prescribe a nostrum, it is fraud, as he could prescribe his own nostrum without paying our fee. He seeks intelligent advice and knowledge, and we have cheated him by giving him unknown mixtures or ignorance. With the aid of an honest druggist, by means of our Pharmacopeia and National Formulary, we hardly need a single proprietary mixture in the medicinal treatment of disease.

Few physicians know the range and compass of these books. They contain sixty cerates, ointments, salves, mulls, petroleums and collodions. Can any one doubt that with this number of greases a good sedative or stimulant ointment could not be selected, or any combination made that was desired? They also offer seventy-seven oils, waters and liniments for external use; certainly all the rubs that there is room for on the human body. There are at least twenty-two simple and antiseptic dusting powders; certainly enough. So much for external remedies.

The Pharmacopeia of 1900 contains two vinegars, seventeen waters, three elixirs, six emulsions, twenty-eight extracts, eighty-five fluidextracts, two glycerites for internal use, about twenty liquors or solutions for internal use, four mixtures, six oleoresins, forty-five oils, fourteen pills, nine powders, four resins, twenty spirits, twenty-nine syrups, sixty-four tinctures, nine troches and ten wines; while the National Formulary contains one vinegar, sixty-four elixirs, nine emulsions, two extracts, thirty-six fluidextracts, four glycerites, more than thirty-eight solutions, eighteen mixtures, twenty-one pills, nineteen powders, three spirits, thirty-seven syrups, twenty-seven tinctures, and ten wines. No sane person would advocate using all of this heterogeneous mass of preparations, but every physician can, with the aid of his druggist, select the few formulas that he will use that will be as elegant and pleasant methods of giving drugs as proprietary preparations, and, moreover, will represent guaranteed doses of the various ingredients of the formulas selected.

While the use of some of the preparations above named is advised, it should be understood that it is much better to combine one's own prescription to fit the individual case, but these official preparations preclude the necessity for using proprietaries.

Now, what are the bugaboos that make the physician reach for the proprietary preparations?

First, tonics: The first drug to consider is iron, and the proprietary preparations of organic iron are legion. There is not a single, good, substantial reason why we should order any one of them, and certainly the profit ordered by physicians to be paid by trusting patients to foreign manufacturers is unjustifiable. No iron will act any better than an inorganic iron. If there is an idiosyncrasy against it, smaller doses should be used, and, ordinarily, too large doses of iron are given. The reduced iron, the mass of carbonated iron, the pill of the carbonate of iron, the saccharated oxid of iron (*Eisenzucker*) in tablets for children, the tincture of the chlorid of iron, the syrup of the iodid of iron, with ten elixirs in the U. S. P. and N. F. containing iron, and any number of other iron salts can do all in the iron line that it is possible to do. No "patented" iron can do therapeutically what we cannot do with one of the first five mentioned iron preparations.

Now as to beef: Is there any beef preparation made, in recommended daily dose, that can equal a small piece of steak, a little scraped beef *pâte,* a little chopped raw beef, or expressed beef serum? No.

As to other albuminoids and protein foods, a little milk, a little white of egg, a little oatmeal gruel, and many other simple nutriments preclude the necessity for their use, except in rare instances.

We do not need a "patented" bitter tonic. We have the compound tincture of gentian, the compound tincture of cinchona, and the tincture of nux vomica, in one to five drop doses, and we need for bitter tonic purposes no other.

As to stimulants: It is not necessary to pay for a poor "patented" sherry. We had much better order whisky, brandy, sherry, ale, or champagne, as needed, and the patient will save money and receive better stimulation.

As to digestants: Very rarely is pepsin needed, and pancreatin is of but little value in the stomach. If they are needed, the Pharmacopeia and National Formulary offer several preparations for a choice. Even predigesting powders are furnished by these official books. In other words, the long list of proprietary digestants is not needed.

We do not need the fat and oil emulsion proprietary preparations. The oil emulsions of the U. S. P. and N. F. are sufficient, if we desire them. Straight doses of cod-liver oil are better, and cream, butter and olive oil surpass any fat emulsion. We need no proprietary suspensions of oils, as the U. S. P. and N. F. offer all that are needed from turpentine to castor oil.

Tasteless quinins are mostly useless, and the various methods at our disposal of giving quinin allow us to surmount all difficulties of age and taste and we need no proprietary help other than the free-to-all elegance of the elastic capsule.

We do not need the legion of "patented" preparations of glycerophosphates and lecithin, as the National Formulary furnishes an elixir of glycerophosphates with lime and soda.

Concerning the long list of antipyretic preparations, cough-mixtures, hypnotics, and nerve sedatives, there is but one thing to say, viz., that any physician who thinks he is unable to write the prescription needed for the individual who requires such medication should instruct himself in the method of writing for such drugs and arranging such pharmacally and pharmacologically correct combinations as will suit the needs of his patients. A long list of antipyretic "coal-tar" drugs is not needed. The official antipyrin, acetanilid and acetphenetidin (phenacetin) are all that need to be used. Caffein, camphor, soda, phenyl salicylate (salol), and any other drug can be combined with them, if desired. As to cough-mixtures: What codein, ipecac, ammonium chlorid, potassium iodid, terpin hydrate, and syrup of hypophosphite cannot do, cannot be done at all with drugs. Any or all of these should be given with absolute omission of the ancient, nasty, sweet and nauseating syrups. There are no combinations of hypnotics that cannot be better made by ourselves, and for much less cost to our patients.

None of this should prevent a physician from trying a new drug if he thinks it is an honest one, because we should be ever ready to make use of a valuable discovery, but never to further a fraud. Such a new drug should be ordered straight or used only in our own combinations, and never in a ready-made mixture offered by the firm interested.

Nerve sedatives for hysteria and allied conditions are either useless and act by suggestion, or they carry the danger of forming a drug habit. We should write for our own patients our own prescriptions.

Among the various uric acid and gout-curing preparations fraud and credulity are rampant. The regimen and extra water abolishes symptoms, if anything is done at all, and of all waters, pure distilled water is the best. It is not intended to assert that a sojourn at a water health resort is not of first-class advantage, because it is. A change of climate, a change of water, a change of food (cooked differently, hence often chemically different), a change of life and freedom from worry, and a change of exercise are the factors that do good, and not "urate solvents." This is not to declare that minute doses of some chemical ingredient in certain waters, taken for a long time, may not modify metabolism; this must be acknowledged, but it does not alter the absolute falsity of the lithic acid and urate solvent promises.

Next we come to the effervescing preparations, and here we should lean on the druggist. A large number of effervescing preparations are official, but any favorite combination of any physician can be prepared by his druggist to effervesce at a cost much less than the same in proprietary bottles that are blazed to show the laity that they are proprietary, and unless the druggist is particularly careful, carry a lot of quack literature into the family, which is read with avidity, "as the doctor ordered it," all for a price which furnishes a splendid profit to the concerns making these preparations, but hardly enough profit to the druggist for shelving them.

As to disinfectants: Again the Pharmacopeia and National Formulary come to meet our needs with mercuric chlorid, phenol, hydrogen peroxid, formaldehyd solution, potassium permanganate, chlorinated lime, and various solutions; and the druggist is ever ready to make in large quantity, or strong for solution, any disinfectant that we may select. Also, he can readily make any alkaline mouth-wash that we may elect, if the two that are official are not satisfactory.

The art of writing our own prescriptions is only a question of a book or two, a little study, careful selection of official preparations, a few heart-to-heart talks with a trusted druggist, and the thing is an accomplished fact.

DIABETES

The diabetes produced in animals by complete or almost complete removal of the pancreas so closely resembles human diabetes in its essential features that it is reasonable to hope that any method which will cure the former will also be of use in the latter; any light which may be obtained on the experimental form will also help to a better understanding of the human disease. We commented some time ago[1] on the futile efforts which had been made to control diabetes in animals by the administration of extracts of the pancreas and compared them with the similarly futile efforts to treat human diabetes in this manner.

Hédon,[2] one of the most experienced and critical experimenters in this field, has recently made some important observations on experimental diabetes. He has long taken a critical attitude toward the theory of an internal secretion of the pancreas, maintaining that it could not be considered as proved until an experiment could be devised in which the experimental diabetes could be checked by the administration of a product obtained from the pancreas. He speaks of the negative results obtained from the injection of various extracts of the pancreas, of the serum from the pancreatic veins, etc., and remarks that he was near believing the process to be an irreversible one. He had found that when a crossed circulation was established between a normal and a diabetic dog, sugar disappeared from the urine of the latter. Such a result would have been interpreted by a less critical observer to mean that the internal secretion of the normal dog had checked the diabetes in the other dog. Hédon, however, found that when the circulations of two diabetic dogs were crossed there was also a diminution of the glycosuria; such a result suggests that the effect was due to an action on the permeability of the kidneys for sugar.

In the present experiments a portion of the pancreas of a normal dog was inserted into the circulation of a diabetic dog. When the carotid and jugular were used there was no effect on the glycosuria of the diabetic dog; when, however, the pancreas was inserted into the circulation of the spleen, the sugar almost disappeared from the urine after some hours but returned when the *connection between the two animals was broken.* Thus a normal pancreas checked the glycosuria only when it was so placed that its internal secretion entered the portal circulation directly.

Hédon and others had found that the injection of blood from the pancreatic vein of a normal dog into the general circulation of a diabetic dog had no effect on the glycosuria of the latter; he now finds, however, that if the blood be injected into a mesenteric vein of the diabetic dog the glycosuria falls for a time almost to zero. In all of these experiments, however, there was far less diminution of the sugar in the blood than of that in the urine; the first effect of the pancreatic secretion was to render the kidney less permeable to sugar.

These experiments are significant. They constitute the first demonstration that an internal secretion of the pancreas can check a diabetes already established; this was accomplished, however, under conditions so far removed from anything which can be realized in therapeutics that an effective treatment of human diabetes by pancreatic extracts seems more remote than ever.

These experiments also emphasize the importance of the liver in diabetes and lend further support to the view, which seems to be gaining many adherents, that the cause of diabetes is to be sought in an overproduction of sugar (chiefly in the liver) rather than to a diminished oxidation of sugar; according to this view the function of the internal secretion of the pancreas is to inhibit the production of sugar rather than to facilitate its consumption.

These, and some earlier experiments of Hédon, go far toward explaining the almost uniformly negative results from the use of pancreas in human diabetes; they also make it very probable that the favorable results reported by three or four writers had no connection with the pancreas which had been administered. In some of the cases the beneficial effects were stated to continue for long periods after the administration of the pancreas was discontinued. An animal becomes diabetic within an hour or two after removal of the pancreas; that is, the secretion disappears from the blood exceedingly rapidly even under the most favorable conditions of secretion. These alleged favorable results constitute the sole "evidence" that has yet been offered in support of the view that the internal secretion of the pancreas is absorbed when administered by the mouth. It may be considered as certain that the improvement noted in such cases was in no way dependent on the internal secretions of the pancreas administered.

It is well to remember the caution recently emphasized by Sewall,[3] who says: "It is, of course, unnecessary to dwell on the well-known fact that the clinical course of diabetes mellitus is at times apparently subject to amelioration under a great variety of conditions and remedies which probably have no specific relation to the pathologic process."

---

[2] Hédon: Compt. rend. Soc. biol., July 14, 1911, p. 124.

[3] Sewall: Am. Jour. Med. Sc., Sept. 11, p. 321.

It should be added, however, that, according to Falta,[4] there is a small group of cases of diabetes in which the administration of pancreas by the mouth gives good results; but in these cases there is some interference (usually the result of lithiasis) with the secretion of the pancreatic juice into the intestine. These cases are not comparable to ordinary diabetes.

COMMERCIAL ANTISTREPTOCOCCUS SERUM

In these days of the preparation of immune serums by proprietary houses, it is obvious that many such products will be of problematical virtue; so that a recent study of various commercial antistreptococcus serums by Weaver and Tunnicliff[1] possesses a distinct practical value, aside from the theoretic interest always attaching to such work.

In a previous preliminary report[2] these investigators had announced their almost complete failure to find any action of such serums on laboratory animals; and it is encouraging to note that the results of their more complete later work are at variance with this, and show, in several of the commercial preparations, a distinct protective power.

The first part of their work consisted in the testing of fresh specimens of antistreptococcus serum, obtained from one of the commercial houses, as soon as possible after its withdrawal from the animals. Such serums were tested both for their protective power in guinea-pigs against later doses of virulent streptococci, and for their content in opsonin. The latter was found to diminish fairly rapidly, until at the end of a month it had disappeared completely. It could be almost completely restored, however, for variable periods afterward by the addition of dilute fresh normal serum, and the protective power for animals was found to coincide quite closely with this period of capacity for reactivation. The injection of the serum into the animals resulted, as might be expected, in a rise of their opsonin for streptococcus, and also of the phagocytic activity of their leukocytes, and this rise of phagocytic power seemed to be specific for streptococcus. The duration of the protection was about eight days—corresponding very closely with the period of increased opsonin content in the blood.

Five commercial antistreptococcus serums, three of American and two of European preparation, were studied similarly. Of these, both of the foreign and two of the American serums protected guinea-pigs against a minimal lethal dose of streptococci in quantities of from 1 to 6 c.c. The third American serum had no evident protective action. Of course, the administration of a correspondingly large dose to man would be out of the question, but there are apparently reasons for believing that relatively smaller doses may be efficient in cases of human infection; for it was found that the immune serums were reactivated more readily and to a greater degree by human than by guinea-pig serum, so that the same amount may well possess a greater protective power in man than in the guinea-pig. And the usually localized and more prolonged human infection presents an entirely different, and possibly less difficult, problem, than the very acute generalized infection of laboratory animals. Clinical observation has shown, however, that large doses are most effective, and concentration of the serum might be of great value. The possibility of such concentration is pointed out by Weaver and Tunnicliff, who found the antibodies to be united with the pseudoglobulins of the serum as is the case with diphtheria antitoxin.

In view of the fact that one of three of the American serums was found apparently quite inactive, the recommendation of the investigators, that a guarantee as to efficiency be furnished, similar if possible to that of diphtheria antitoxin, seems very reasonable. With such an assurance of reliability, it is probable that the antistreptococcus serums would rapidly acquire a greater importance than their present uncertainty gives them. In this connection, however, it may be well to emphasize the necessity for making an accurate bacteriologic diagnosis previous to the use of such serums, as without this it is impossible to expect consistent results.

EFFECTIVE GARBAGE DISPOSAL

Until lately American practice in the matter of garbage disposal has not been a matter for national pride. Two methods have been common: unsightly, malodorous piles of decomposing refuse have been — in some places still are! — allowed to accumulate in the vicinity of dwellings, or cheap, ineffectual "disposal plants," installed and operated by greedy or dishonest private contractors, have been run for a few years and then allowed to lapse into well-earned oblivion. Neither procedure is creditable to a civilized state. There are now signs that the era of slovenliness and waste in this as in many other municipal activities is drawing to a close. In many places local conditions are being studied by unpaid competent commissions rather than exploited by junketing aldermanic committees. A beginning has been made in establishing high-grade modern plants under expert supervision and in operating them under expert management, which is just as important.

As the reports of some of these plants are coming in we can see more clearly than ever what a mess has been made in the past by the representatives of the people in dealing with this question. There is really no need for a continuance of the offensive and wasteful methods that have been commonly employed in this country. The best expert advice backed by practical experience with American conditions is now available at a moderate price and there is no excuse for any community placing itself in the hands of self-seeking contractors and promoters.

---

[4] Falta, W.: Therapy of Diabetes Mellitus, Arch. Int. Med., 1909, iii, 160.

[1] Weaver and Tunnicliff: Jour. Infect. Dis., 1911, ix, 130.

[2] Preliminary Report of Investigations of Serums and Vaccines for Streptococcus, Staphylococcus and Pneumococcus Infections, The Journal A. M. A., Jan. 25, 1910, p. 257.

At least two methods of garbage disposal have proved effective in typical American cities: incineration and reduction. In the incinerating type of plant all kinds of refuse, ashes, paper, rags, scraps of food, kitchen waste, etc., are fed together into crematories and burned. In European works of this type the heat generated by the combustion with a forced draft is a source of considerable revenue. One of the best examples of an incinerator plant in this country is the Milwaukee incinerator, which has been in full operation since May, 1910. Constructed and operated under excellent engineering control, this plant may well serve as a model for other cities.[1] At the old Milwaukee plant the cost of disposal reached as high as $1.37 per ton of garbage, while the cost at the new plant is less than 60 cents per ton. If the excess supply of steam generated at the plant is economically utilized the actual cost will be further greatly reduced.

In garbage reduction works the sorted garbage is passed through various digestors, tanks and roller presses with a view to extracting the valuable portions, especially the fats and the nitrogenous matters. The process needs careful management on account of the offensive gases generated during the treatment. The prevention of a nuisance entails some expense, and hence privately installed reduction works operated for commercial purposes often give rise to much justifiable complaint. Municipal plants constructed with an eye to the comfort of the citizens rather than the pockets of contractors are likely to be much more effectively operated than private ones, as shown by the experience at Columbus, Ohio. The Columbus plant, put in operation in July, 1910, is the first reduction plant in this country designed and constructed by a municipality.[2] "It was not the intention in designing the Columbus plant to try experimental machinery, but rather to assemble to best advantage machinery of known and tried types and only such as had proved most satisfactory in other plants." Successful financial operation of this plant appears in the fact that it netted $2,000 a month for the first six months.

The reasonable and businesslike way of approaching the garbage disposal question seems therefore to be the employment of a reputable and competent engineer to examine local conditions and report on such topics as the most economical routes for collection and transportation, the establishment and location of one or more centers for disposal and the final method of treatment—incineration or reduction—best suited to the amount and nature of the refuse gathered. Small towns should beware of the man with patented machinery. In all cases the expert adviser is better than the quack.

THE CHOICE OF A MEDICAL SCHOOL

At the present time doubtless hundreds of students are wavering in their choice of a medical school—a choice which is of the utmost importance to their future welfare. Before the selection of a medical school is made, the student should inform himself regarding the legal requirements for the practice of medicine, which have been undergoing many changes during the last few years. It is well known that the legal control of the practice of medicine in this country rests, not with the national government, but with the individual states, and that the forty-nine states and territories differ widely in their requirements. It is extremely important, therefore, for the student to know what qualifications he must possess in order to secure a license in the state where he desires to practice. For example, he should know that in order to secure a license in Colorado, Indiana, Iowa, Minnesota or North Dakota, he must have had two years of collegiate work or its equivalent, and that in Connecticut, Kansas, South Dakota and Utah he must have completed one year of collegiate work before beginning the study of medicine. Furthermore, if he desires to secure a license in any of the above-named states or in any one of the nineteen others, he must take his medical training in a college which is considered a "reputable" institution, or one which has been "registered" in the state where he expects to locate.

State boards have various methods of determining what colleges are "reputable." Some make their own inspections, either in person or by proxy; others base their judgment on the reputation held by the colleges; some require that the institution hold standards equal to those of the Association of American Medical Colleges, and of late several states have decided to recognize only those colleges which are listed in Class A by the Council on Medical Education of the American Medical Association.

Each year the requirements by state boards are becoming more exacting. The number of boards which will require one or two years of college work as the minimum of preliminary education will doubtless increase and the requirements regarding the equipment and facilities of medical schools will become more rigid. As will be noted in the Current Comment Department below, any medical college, to be registered in New York after Oct. 1, 1912, must have at least six salaried instructors devoting their entire time to college work besides having ample apparatus and equipment.

Another requirement by state boards which the prospective medical student must consider seriously is that of the state license examination. Year by year these examinations are becoming more severe and the student should use much care in selecting a medical college which will best prepare him for those examinations. Information on this point can be obtained by a careful study of state board statistics such as are published annually in The Journal.[1] It would be a serious matter indeed to select a medical school having a high percentage of failures of its graduates at state license examinations when doubtless for the same expenditure of time and money the student could secure a training in a first-class medical college.

---

[1] A full description of the Milwaukee incinerator, with drawings and operating data, is given in the Engineering News, July 21, 1910.

[2] For description, with diagrams and photographs, see Engineering News, *Nov. 17, 1910.*

The student may well be guided by the reports on medical colleges also published from time to time in The Journal. From the investigations made by the Council on Medical Education, the colleges having what was considered an ample corps of teachers and satisfactory laboratories, equipment and clinical facilities, were listed as acceptable schools, that is, in Class A. Schools which were not so well equipped, or which were considered unsatisfactory were listed respectively in Classes B and C. Of the Class A colleges, twenty-eight[2] are now requiring two or more years of collegiate work for admission. The student will not be making a mistake should he select one of these twenty-eight schools, the diplomas from which are acceptable at present in practically every state of the Union. The student having had less than two years of collegiate work, should investigate carefully, before deciding on a medical school, the requirements of the state or states wherein he would like to locate. Furthermore, he should consider whether it would not be better for him to secure the additional preliminary education which would admit him to a medical school wherein he could get the best possible medical training and from which he could secure a diploma making him eligible for a license in any state of his choice. Disappointed indeed will be that student who, after having spent a large amount of time and money, finds on graduation that his diploma is not recognized in a large number of states.

Current Comment

MAGAZINE ARTICLES WHICH ARE WORTH WHILE

An important factor in the crusade for better health conditions is the active interest shown in this question by the better class of popular magazines. The part taken by *Collier's* and the *Ladies' Home Journal* is well known. In the last two or three years, many excellent articles on health matters have appeared in other magazines. Four articles in current periodicals are worthy of special mention. In the September number of the *Delineator*, Samuel Hopkins Adams, under the title of "The Health Master" gives in narrative form some plain truths about drug victims produced by "patent medicines" and soft drinks. In the October *Hampton-Columbian*, O. K. Davis gives the details of "The Case of Dr. Wiley" and the facts regarding the conspiracy to secure his discharge. In the October *Pearson's*, Earl Mayo discusses, under the title of "Public Health vs. Private Gain," preventable sickness and the duty of the government and, incidentally, the efforts that are being made to prevent the establishment of a national department of health and the reasons for the opposition. In the *Outlook* for September 23, the same writer has an excellent article on "The Work That Kills," a discussion of occupational diseases and means for their prevention. Such articles, by the best representatives of the modern school of American magazine writers, are of great educational value and are sure to do good. It is fortunate that our popular magazines, not willing to be confined to sentimental stories and trivial entertainment of their readers, have realized their great possibilities as an educational force and are usually to be found on the right side in any great battle for the public good. Such articles as the four mentioned are of inestimable value in enlightening the public on the needs and the methods of health reforms. More light, more knowledge, more education of the people must be furnished until the demand for federal action for the preservation of life becomes irresistible. It is by such means that lasting reforms can be brought about.

RELIGION AND QUACKERY

For years the religious press reeked with unsavory advertisements of nostrums and quacks of varying degrees of fraudulency and indecency. Public opinion finally forced the more influential church papers to throw out this class of advertising and to-day, except for some of the more insignificant publications, the religious journals are practically free from the blight of "patent medicine" advertisements. That quackery still seems to possess a peculiar fascination for the clergy, however, was recently shown in an episode that occurred at Kansas City, Mo. That city is the unfortunate possessor of a quack named Carson—Hiram Carson, or as he calls himself "Dr. C. H. Carson." This charlatan has grown rich, thanks to a venal press and the large supply of gullible sick. He used to "treat" by means of "vital·force," developed by rubbing his victims with vaselin mixed with red pepper. The tingling produced by the red pepper was, he assured his dupes, the "vital force." Later he improved on this "treatment" and had his assistants give out slips of tissue paper that he had "magnetized." These slips the patients were instructed to pin on their nightgowns between the shoulder-blades! Carson is now operating what he calls the "Temple of Health," and advertising heavily. As a means of drumming up trade Carson occasionally gives elaborate "receptions" at his "Temple of Health," to which the curious are invited. A little while ago a meeting of this kind was held at which, as a crowning advertising stroke, Carson got the pastor of one of the leading Congregational churches of the city—the Rev. J. B. Silcox—to give an address! This address and other details of the "reception" occupied nearly two columns in the Kansas City papers of the following day, and although a paid advertisement, the article was set up in news-matter style. Why a reputable minister of the gospel, whose own church membership is strictly high-class and, we are informed, includes some of the best-known medical men of the city, should endorse such a blatant quack as Carson, is a mystery. Every intelligent layman in Kansas City knows that Carson is a humbug and that his system is a fake. Every man in that city also knows, or could know, that Carson's only claim to the title "doctor" lies in his possession of a "diploma" from as wretched a mill as ever ground out parchments—the American Health College of Cincinnati, long since defunct, thank heaven! If there is one class of men more than another that should stand between suffering ignorance and the machinations of the miserable harpies of the Carson type, it is the ministry. If there is one man more than another who should expose the deception and covetousness of the quack, it is the man who professes to follow the teachings of Him whose voice was always raised against shams and cheats and the cupidity of avarice. Yet we have, in the address of Rev. Mr. Silcox, the unedifying spectacle of a Christian clergyman lending the influence of his cloth and personality to further the cause of one who fattens by deceiving the sick and suffering.

ADVANCE STEP IN MEDICAL EDUCATION BY NEW YORK

About a decade ago the Revised Statutes of New York fixed a requirement, among others, that any institution to be ranked as a college should have "at least six professors giving their entire time to college and university work." The investigation made by the Council on Medical Education revealed the fact, however, that the Board of Regents did not make this rule apply to medical colleges of New York or of any other state. It remained for the Council on Medical Education, in 1910, after having completed two tours of inspection of the medical schools in the United States, to publish an outline of the essentials of an acceptable medical college; this included the requirement of six full-time, salaried professors. The Council also published the following definition of a medical college, basing it on the New York law referred to above: "An institution to be ranked as a medical college must have at least six professors giving their entire time to medical teaching, a graded course of study of four full years of college grade in medicine, and must require for admission not less than the usual four years of academic or high school preparation or its equivalent in addition to the preacademic or grammar school studies." As will be seen by a news item which appeared last week,[1] the above definition has been adopted by the New York regents in an amendment to their revised rules, this amendment providing that, after Oct. 1, 1912, every medical college to be registered in New York as maintaining a proper medical standard must have at least six full-time instructors besides ample apparatus and equipment. The argument advanced in the regents' report for this amendment is as follows: "The value of a medical education like the value of a liberal arts education is dependent as much or more on the teachers in the medical college as on the material equipment of the institution. Certainly at least six expert, thoroughly trained instructors in the laboratory branches of the medical course, salaried so that they may devote their entire time to instruction and to that research without which they cannot well keep up with the rapid progress being made in their subjects, is not too many teachers to require for a medical school that is to be recognized in this state as thoroughly preparing for the profession of medicine candidates who are to receive a degree that will admit them to a licensing examination." The influence exerted and the prominent position occupied by the New York Education Department in the control of educational institutions in the United States makes this decision one of much importance, and one that will aid in the development of better teaching in the medical schools of this country.

LET CONGRESS INVESTIGATE THE "MEDICAL TRUST"

In the Medical Economics Department[1] appears an open letter from Mr. George P. Hampton, secretary of the Conference of Progressive State Granges to Senator John D. Works of California. Mr. Hampton's letter is worthy of note for two reasons: First, it definitely and officially contradicts the statement made by Senator Works, in his astounding speech in the United States Senate in defense of Eddyism, that the National Grange had repudiated its endorsement of a national department of health. Mr. Hampton proves that the National Grange really reaffirmed its previous endorsement. Second, the letter contains in its closing paragraphs the following pertinent remarks:

> "Christian Scientists fear the consequences that would follow the enactment of such legislation as the Owen bill proposes. If that fear is well founded, and your belief that the American Medical Association is a medical trust is well founded, is it not time that the country knew these and all the facts relating to this burning question? What possible better means have we than a rigid Congressional investigation by a committee specially organized for that purpose? The House of Representatives, as at present constituted, is believed to be honestly desirous of serving the people. It is investigating the trusts, probing into the expenditures of the various departments of the government, and why should it not have a committee on health and thoroughly investigate this matter of such vital importance to all the people. Surely the Christian Scientists are not opposed to honest investigation by a committee having power to probe every charge and countercharge to the bottom."

Mr. Hampton's position is a thoroughly sound one. If the American Medical Association is a "trust" or if it is endeavoring to create a trust, certainly the people should know it. If the physicians of the country are seeking a health department so as to create positions for themselves, and not to stamp out disease and save human lives, the public should know it. On the other hand, if the American Medical Association and the medical profession are earnestly and honestly striving to increase our knowledge of the cause and means of prevention of epidemics and to wipe out preventable disease, then the people should know this and should lend their aid in this life-saving campaign. As Mr. Hampton says, "Why should it (the House of Representatives) not have a committee on health and thoroughly investigate this matter?" Why should not the work of the American Medical Association be investigated? Why should not Congress be able to tell the American public the truth? Surely the needless loss each year of 600,000 lives is of as vital importance to the people as the price of sugar, tobacco or steel rails. Will Congress "investigate" the American Medical Association and its work? If it will, the books and records of the Association will gladly be produced and its officers and members will willingly testify, nor will any order from the courts be necessary to insure their presence. Investigation and credit for the work it has done and is now doing is exactly what the Association most desires, since it knows that the more the people know of its work for the public good, the more it will enjoy the confidence and support of the public.

Medical News

ALABAMA

Dispensary Open.—St. Vincent's Free Dispensary, Birmingham, was opened September 5. It is located in the basement of the new wing of the hospital, and is to be open from 2 to 4 p. m., daily excepting Sunday.

Personal.—Dr. Edward B. Bailey, Demopolis, luckily sustained only slight injury when his automobile fell into a 10-feet ravine, September 6.——Dr. Charles M. Moore has succeeded Dr. Rhett Goode, resigned, as health officer of Mobile.——Dr. Claude L. Murphree has been made meat and milk inspector of Gadsden.

ARKANSAS

Sanitarium for Colored Patients.—Dr. Claude M. Wade, Hot Springs, has secured the control of the Pythian sanitarium and bath house, which he proposes to use for the care of sick and indigent colored people who come to Hot Springs.

Personal.—Dr. James L. Greene assumed charge of the State Hospital for the Treatment of Nervous Diseases, Little Rock, August 31.——Dr. Harry C. Stinson, superintendent of the State Hospital for the Insane, took formal charge of the Confederate Home, September 1.——The home of W. T. Gabbert, West Forks, was destroyed by fire, September 12.

CALIFORNIA

State Branch Hygienic Laboratory to be Opened.—Arrangements are being made for the establishment of a branch hygienic laboratory in Los Angeles, where Pasteur treatment may be administered, and also where investigations regarding violations of the pure food law and of water pollution may be conducted.

University to Have an Isolation Hospital.—The board of trustees of Leland Stanford, Jr., University, Palo Alto, has granted a site for the erection of an isolation hospital for the segregation of students with contagious diseases. These cases have heretofore been quarantined in dormitories or private rooming houses. The hospital is to cost $10,000.

Personal.—Dr. Leonard E. Stocking, Agnew, superintendent of the Agnew State Hospital, has been given three months' leave of absence by the board of managers.——Dr. Harold Brunn, San Francisco, who has been seriously ill with pneumonia, is reported convalescent.——Dr. Douglas Brown, formerly of New York and Panama, has been appointed resident physician to the Spreckels Sugar Company, Spreckels.——Dr. J. Auburn Wiborn, San Francisco, fractured his right leg in a fall down an embankment at Klamath Springs recently.——Dr. Thomas R. Meux, Fresno, was seriously injured in a runaway accident, September 4.——Dr. Washington Dodge has been elected a trustee of the San Francisco Free Library.

COLORADO

Loving-Cup for First-Aid Contest.—A silver loving cup is offered by Dr. Thomas J. Forhan, Trinidad, for the best exhibition of first aid to the injured work by a team of school boys under the age of 16. The contest is open to the boys of any school in Las Animas County, and will take place at the time of the county fair.

Personal.—Dr. Benjamin F. Wooding, Denver, has retired from the State Board of Health.——Dr. Carl A. Helgeson, Grand Junction, has been reappointed inspector for the board of health of New York City.——Arnold Stedman, Denver, announces that he decided not to accept appointment as member of the State Board of Health.——Drs. John E. Sawyer, Denver, and Robert Elwood have filed incorporation papers for the opening of a sanitarium in Boulder, for the treatment of rheumatism.

GEORGIA

Officers Resigned.—At the adjourned meeting of the Clarke County Medical Association at Athens, September 9, the resignation of the president, Dr. Daniel H. DuPree, Athens, and the secretary, Dr. John Gerdine, Norfolk, Va., were accepted. Dr. Singleton S. Smith was elected president, and Dr. Samuel C. Benedict, secretary.

Pellagra Hospital Open.—Len G. Broughton, pastor of the Institutional Church, Atlanta, has opened a pellagra hospital in connection with the church. The institution will accommodate twenty-one patients. The permanent free clinic for the diagnosis and treatment of pellagra has been opened by the Atlanta Associated Charities in Room 708, Gould Building, and is open on Wednesday and Saturday from 5:30 to 6:30 p. m.

IDAHO

Personal.—Dr. Harley E. French, Moscow, has been elected professor of anatomy and dean of the medical department of the University of North Dakota, Grand Forks.——Dr. Arthur R. Soderquist, Idaho Falls, was thrown from his automobile recently and sustained painful injuries.——Dr. F. S. Wright has been appointed health officer of Salmon City.

ILLINOIS

Bequests to Hospital.—By the will of the late Emanuel Frankenthal, Chicago, $2,000 is bequeathed to St. Luke's Hospital, and a similar amount to Michael Reese Hospital.

Clinic for School Children at Evanston.—Dr. George W. Boot, president of the staff of the St. Francis Hospital, Evanston, announces that the hospital has arranged for a free clinic for school children needing attention on account of conditions found by school inspectors. The clinic will be held each Saturday at 1:30 p. m.

Tuberculosis Clinic Established.—The Springfield Tuberculosis Association held its first evening clinic between 5 and 6:30 p. m., September 14, at the dispensary, 717 East Washington Street. Evening clinics are to be held on every Thursday, to accommodate patients who are unable to attend during the working hours.

Personal.—Dr. J. N. Thresh, Danvers, who has been ill at St. Frances Hospital, Peoria, has returned convalescent.——Physicians of Mattoon gave a dinner, September 14, in honor of Dr. Cleaves Bennett, who has removed to Champaign.——Dr. Harvey L. Hensley, Oakwood, is reported to be critically ill.——Dr. Charles R. Spicer, Aurora, has been elected chief medical examiner of the Yeomen of America.

Hospital Notes.—The village council of Oak Park has refused permission to build the West Suburban Hospital in that village, on the ground that the management had failed to obtain the necessary consent of the neighbors to the erection of the building.——At the annual meeting of the officers of Proctor Hospital, Peoria, Mr. Oliver J. Bailey was reelected president. A memorial tablet was placed in the hospital in memory of the late Dr. John Murphy.——Dr. and Mrs. Edmund F. Cleveland, Dundee, have announced that they will furnish the dormitories on the first floor of Sherman Hospital, Elgin, now occupied by the nurses. The dormitories are to be remodeled and divided into six rooms, which will be used as wards for women and children. The gift is in memory of their daughter.

Chicago

Institute Does Not Employ Solicitors.—The Chicago Tuberculosis Institute announces that no solicitors are employed to collect money for the organization. The reason for this announcement is that two men are reported to have been soliciting money for the alleged benefit of the institute.

Neighborhood Health Lectures.—The Chicago Medical Society plans to give neighborhood health lectures throughout the city during the winter months. Public lectures have been given in the public library in previous years, and it is now proposed to extend the scope of these lectures by having talks along health lines made in various sections of the city, and in school houses, if they may be obtained from the board of education.

Personal.—Dr. John Ridlon has been elected consulting surgeon for the Newport (R. I.) Hospital.——Dr. William S. Sadler sailed for Europe, September 23.——Dr. and Mrs. Charles S. Bacon and family, Dr. and Mrs. Alexander F. Stevenson and Dr. and Mrs. Arthur H. Geiger have returned from Europe.——Dr. Alexander H. Ferguson has taken in his first assistant, Dr. James J. Monahan, as his partner, and will take a rest for a year.

INDIANA

Wills Estate to Medical College.—The late Dr William Flynn of Marion has willed his entire estate, valued at about $30,000, to the Indiana Medical College, in which he was a member of the faculty for many years.

Grant County Hospital.—The Grant County Hospital Association has requested the county commissioners to make an appropriation of $50,000 for a county hospital to be built at Marion. Mr. Robert J. Spencer of that city has offered a site for the hospital, free of incumbrance.

Personal.—Dr. George M. Kakin, LaPorte, believed to be the oldest active practitioner in Indiana, is reported to be critically ill.——Dr. Adoniram J. Banker, Columbus, is reported to be critically ill in Indianapolis.——Dr. Hugh D. Wood, Angola, was seriously injured in a fall on a slippery sidewalk, September 18.

Hospital Trustees Resigned.—At a meeting of the Good Samaritan Hospital Board, held in Vincennes, September 5, a petition was read, signed by thirty-five members of the Knox County Medical Society, and a resolution of the Vincennes physicians was presented at a formal meeting which called for a radical change in the management of the hospital. With the expressed desire to reestablish harmony, three members of the board of trustees resigned.

IOWA

Personal.—Dr. Harley G. Ristine, Fort Dodge, was seriously injured while cranking his automobile, September 20.——Dr. Daniel Johnson Glomset has been placed in charge of the pathologic and bacteriologic departments of Drake University.——Dr. Paul Eugene Lineback has been appointed instructor in anatomy in the Drake University, Des Moines.——Dr. Jasper E. Guernsey, Olin, was injured in a runaway accident in Chicago, September 8.

Medical Library for Sioux City—Dr. John E. Garver donated his medical reference library to the Sioux City Medical Library Association. Several others have made similar gifts, and it is hoped that the library will become a permanent institution.

KENTUCKY

Tri-Medical Society Organized.—Physicians of Logan, Simpson and Warren Counties met at South Union, September 12, and organized the Tri-Medical Society.

State Health Car.—The Kentucky Association for the Study and Prevention of Tuberculosis is touring the state with a car fitted up as a traveling health exhibit, in charge of Mr. Eugene Kerner, secretary of the state association, and an assistant. The car is well stocked with charts, mottoes and model houses, showing where the dangers from diseases lie and how they can be prevented; and an illustrated lecture on "What Everybody Ought to Know About Consumption" is delivered at each stopping place.

LOUISIANA

Bequest for Home for Incurables.—By the will of the late Joseph E. Burguieres, $50,000 is devised to establish the Burguieres Home for Incurables, which is to be placed under the charge of the Sisters of Charity of New Orleans.

New Department in Medical College.—The Medical Department of Tulane University announces the inauguration of a department of tropical medicine, hygiene and preventive medicine, beginning October 1, in charge of Dr. Creighton Wellman and staff. Laboratory courses, clinics and lectures will be given in the regular junior and senior classes, in addition graduate courses are offered, for which certificates will be issued, counting toward special degrees to be created as soon as the Tulane School of Tropical Medicine is in force.

Antituberculosis Work.—During the last year the Louisiana Antituberculosis League has abandoned its former camp at St. Tammany Station, which was left practically inaccessible on account of the abandonment of that portion of the railroad, and has opened a new and well-equipped sanitarium for curable cases at Camp Hygeia in the same parish, 5 miles west of Slidell.——On September 4 the cottages at Camp Hygeia, erected by the Pythian Antituberculosis League, the Junior Order of United American Mechanics and two councils of the Daughters of America, were formally dedicated.——A site for the cottage to be erected at Camp Hygeia by the union printers' organization has been selected.

MASSACHUSETTS

Measles.—The White Star steamer *Romanic* from Mediterranean ports reached quarantine September 7, with three cases of measles aboard, but no indication of cholera. The steerage passengers were landed at Gallup's Island, where they were detained for forty-eight hours.

Personal.—Dr. Newell C. Bullard, North Attleboro, is reported to be in a serious condition at the Emerson Hospital, Boston, as the result of an automobile accident.——Dr. William J. Gallivan, Boston, former chairman of the Boston school board, has been selected for head of the bureau of school hygiene, under the direction of the Boston Board of Health, vice Dr. Paul Carson, resigned.——Dr. Francis X. Crawford, South Boston, has been appointed chief physician of the board of Boston, vice Dr. William M. Gay, resigned.

MICHIGAN

Banquet to Dr. Carstens.—A complimentary banquet was given by the Wayne County Medical Society, September 26, at the Hotel Cadillac, Detroit, in honor of Dr. James Henry Carstens.

Officers Installed.—At the first meeting of Wayne County Medical Society, September 18, after the summer vacation, the reports of the retiring officers showed that the society has 525 active members, an increase of 243 during the year; that it has a library of 12,000 volumes; that a nurses' directory of 250 names has recently been added and the café and weekly bulletins are more than self-sustaining. The following officers were installed: president, Dr. Henry O. Walker; vice-president, Dr. Benjamin R. Schenck; and secretary-treasurer, Dr. Robert C. Jamieson.

Personal.—Dr. and Mrs. Louis W. Toles, Lansing, sailed for Europe September 13.——Dr. Eugene W. Mullen, Newberry, formerly a member of the staff of the Newberry State Hospital, has resigned to accept a position in the Agnews (Cal.) State Hospital.——Dr. Francis J. W. Maguire, who has been seriously ill with septicemia, due to an operation wound, is reported convalescent.——Dr. Gilbert V. Chamberlain, Flint, has been appointed a member of the pension board of Flint, vice Dr. Hiram H. Bardwell, resigned.——Dr. Russell P. Wixom has been elected president of the Northeastern Detroit Business Men's Association.——Dr. and Mrs. Leslie G. Rhodes, South Haven, have returned from Europe.

MINNESOTA

Sanitarium Nearly Ready.—The new St. Louis County and Duluth tuberculosis sanitarium, now under construction, will be ready January 1. The main building is already nearly completed.

New Buildings on Campus.—The two new buildings for the University of Minnesota, Millard Hall and the Institute of Anatomy, are progressing well toward completion, and it is expected that they will be ready for occupancy within the next ten months. They are located close to the hospital on the new campus.

Elliot Hospital Dedication.—At the dedicatory exercises of the Elliot Memorial Hospital of the University of Minnesota, September 5, a brief notice of which appeared in THE JOURNAL of September 16, the dean, Dr. Frank F. Wesbrook, Minneapolis, presided. Address was made by president George Edgar Vincent, president of the University of Minnesota; the history of the hospital movement was described by Dr. James E. Moore; Frank M. Elliot spoke on the endowment of the Elliot Memorial Hospital. E. L. Carpenter responded for the donors of the hospital site; Dr. Charles Lyman Greene gave an address on "Educational Value of the University Hospitals;" Drs. Rollo C. Dugan, Eyota; Frank H. Alexander, Barnesville; Edward L. Tuohy, Duluth, responded for the alumni of the university hospitals; Dr. William J. Mayo, Rochester, considered the university hospitals as an economic asset of the state, and Dr. Richard Olding Beard, Minneapolis, spoke on the Training School of Nurses of the University. The cornerstone of the Institute of Anatomy was laid, after which the memorial tablets were unveiled and the keys of the hospital were delivered to the superintendent by President Vincent. The superintendent of the hospital, Dr. S. B. Baldwin, then escorted the visitors through the building.

NEW YORK

Industrial Poisonings to be Reported.—The State Department of Health has called the attention of local health boards to the fact that section 58 of the labor law became a law June 6, and went into effect September 1. This law requires that every medical practitioner attending on or called in to visit a patient whom he believes to be suffering from poisoning from lead, phosphorus, arsenic or mercury or their compounds, or from anthrax, or from compressed-air illness, contracted as a result of the patient's employment, shall send to the Commissioner of Labor a notice stating the name of and full postal address and place of employment of the patient and the disease from which, in the opinion of the medical practitioner, the patient is suffering, with such other and further information as may be said to be required by the said commissioner. If any medical practitioner, when required by this section to send a notice, fails forthwith to send the same, he shall be liable to a fine not exceeding $10. It shall be the duty of the Commissioner of Labor to enforce this section and he may call on the state and local boards of health for assistance. This is the first law of this nature to go into effect on this side of the Atlantic.

New York City

Special Meeting of Society.—The Eastern Medical Society of New York held a special meeting at the Academy of Medicine September 20, at which Dr. Albert A. Gray, Glasgow, Scotland, was a special guest of the society and delivered an address.

Old Ferryboat Becomes School.—The Committee for the Prevention of Tuberculosis has obtained a loan of the old ferryboat *Rutherford* and has had it fitted up as a school for tuberculous children. Here the children do all their school work and have their meals in the open air and there are also some accommodations for older patients. A physician and nurses are in constant attendance.

Monthly Bulletin a Success.—Although this publication has only been in existence about a year the edition has already been enlarged twice and a still larger edition is now contemplated. It is hoped eventually that a copy of the bulletin may be sent to every physician in the city and to teachers, clergymen and social workers as well. Applications for the bulletin may be made to the editor of the *Monthly Bulletin of the Department of Health*, Fifty-Fifth Street and Sixth Avenue.

Buffalo

Ask Appropriation for Indigent Tuberculosis Patients.—The health commissioner has asked the city to appropriate $1,200 for the care of indigent patients suffering from tuberculosis. This money is required for eggs, milk and other supplies.——The department of health has recently appointed six nurses to do field work in tuberculosis. This work was formerly carried on by the district nurses, but the city has decided to take charge of this work.

NORTH CAROLINA

Personal.—Dr. Wyatt P. Exum, Goldsboro, is reported to be seriously ill at his home.——Dr. David A. Stanton, John T. Burrus, William M. Jones, William J. McAnally and James R. Reitzel have been elected members of the board of health of High Point.

Municipal Laboratory Recommended.—At a meeting of the board of health of Asheville, September 14, it was decided to recommend to the aldermanic board that $5,000 be appropriated for the establishment of a city laboratory of which L. M. McCormick, chief of the sanitary department, is to be in charge.

OHIO

Clinic for Children in Dayton.—A clinic for the treatment of children under 3 years has been established by the Dayton Flower and Fruit Mission. The clinic is to be conducted every Monday, Wednesday and Friday afternoon, and will be in charge of Dr. Alvin L. Light.

Child Hygiene Bureau Organized.—At an open meeting of the board of health of Cleveland, September 7, the organization of a bureau of child hygiene was perfected with the appointment of Dr. Henry J. Gerstenberger as chief of the bureau, and Drs. Fred Beckel, Carlos E. Pitkin, Richard L. Jett, C. F. Zantiny and Alvin S. Storey, in charge of the five dispensaries now in operation.

Personal.—Dr. Clayton B. Conwell, Cincinnati, has resigned as superintendent of the Ohio State Sanatorium for Tuberculosis, Mount Vernon, and will practice in Cincinnati.——Dr. Asa C. Messenger has been reelected dean, and Dr. Clark M. Galloway, Xenia, secretary of the volunteer medical and surgical staff of the Ohio Soldiers' and Sailors' Orphans' Home, Xenia.——Dr. Russell H. Wilson, Martins Ferry, has been appointed chief surgeon for the United Fruit Company's hospital at Bocas Del Toro.——Dr. Sterling B. Taylor, Columbus, who has been ill in Mount Clemens, Mich., is reported to be improving.——Dr. Albert G. Henry broke two ribs and sustained internal injuries by a falling wall during a fire in North Baltimore, September 9.

OKLAHOMA

Free Antitoxin.—The State Health Department announces that the free distribution of diphtheria antitoxin to those who are unable to purchase it will soon be commenced.

Personal.—Dr. John O. Butler, Crescent, is reported to be seriously ill with typhoid fever.——Dr. R. R. Smith, assistant city physician of Muskogee, was operated on for appendicitis in Kansas City recently.——Dr. William E. Dicken has succeeded Dr. John W. Riley, resigned, as city physician of Oklahoma City.

PENNSYLVANIA

Dispensary Buys Farm.—The Kensington Dispensary for the Treatment of Tuberculosis has purchased the Lennig farm in Upper Providence township, at an expense of nearly $7,000. The farm contains 141 acres and will be used by the dispensary in its work against tuberculosis.

Official Organ of Medical Society Appears.—The *Dauphin County Medical Academician*, the official organ of the Dauphin County Medical Society and the Harrisburg Academy of Medicine, made its first appearance September 13. The magazine is to be issued on the fifteenth day of each month, and its office of publication is at the Harrisburg Academy of Medicine Building.

Personal.—Dr. Clifton Guy Hughes, Punxsutawney, sustained severe injuries when his automobile was caught between two street cars moving in opposite directions, September 14.——Dr. Charles Long, Altoona, was tendered a banquet and presented with a handsome pipe by a number of his friends, on the occasion of his 70th birthday anniversary, September 12.——Dr. William Le Roy Marks has been appointed resident physician to the Carnegie Technical Schools, vice Dr. Walter B. Orbin, Pittsburg, resigned.

Memorial Hospital Opened.—The J. C. Blair Memorial Hospital, Huntingdon, opened its doors for patients on September 4. Drs. Francis P. Ball, Lock Haven, and Theodore L. Chase of Philadelphia, delivered addresses. Dr. George G. Harman, Huntingdon, was chosen president of the staff and Dr. Harry B. Fetterhoof, secretary.

Receipts of Tuberculosis Day.—Clerks of the Pennsylvania Trust Company and officers of the Berks County Tuberculosis Society have finished opening envelopes and counting the contents, received on Tuberculosis Day for the maintenance of the Neversink Mountain Tuberculosis Sanatorium. Although a number of envelopes are yet to be received, the total reached $5,944.85.

Censorial District Meeting.—The eighth annual meeting of the Sixteenth Censorial District of the Medical Society of the State of Pennsylvania which includes Montour, Snyder, Northumberland, Columbia, was held at Selinsgrove, September 8. Dr. John B. Cressinger, Sunbury, was elected president, and Dr. Luther B. Kline, Catawissa, secretary. Danville was selected as the next place of meeting.

Philadelphia

School Campaign Against Tuberculosis.—The Pennsylvania Society for the Prevention of Tuberculosis has placed its winter campaign of antituberculosis education among the children of the public schools of Philadelphia, which opened September 11, in charge of Dr. Howard Fussell, special demonstrator and lecturer of the society. Dr. Fussell has a tuberculosis exhibit which he will establish at each school, devoting from one to two weeks to a school. The exhibit consists of photographs, pictures and charts, and, in addition, Dr. Fussell delivers talks on hygiene to the children in the various rooms of the schools.

Institute of Anatomy Dedicated.—The dedication of the Daniel Baugh Institute of Anatomy of the Jefferson Medical College was observed with appropriate ceremonies, September 26. Dedicatory addresses were made by Hon. William Potter, president of the board of trustees and Dr. Edward Anthony Spitzka, professor of applied anatomy. At the same time the portrait of Mr. Daniel Baugh, the donor of the building with all modern appliances, was presented by the board of trustees and placed in a conspicuous position in the new institute. Hereafter, the teaching of anatomy and its allied sciences will take place in this building.

Personal.—The following physicians have returned from Europe: Drs. William M. L. Coplin, George Strawbridge, William L. Rodman, James E. Talley, Thomas A. Cope, J. William White and Dr. and Mrs. J. Cardeen Cooper.——Dr. Francis R. Packard was recently elected president of the Board of Medical Examiners, vice Dr. Henry Beates, Jr., resigned.

TENNESSEE

Compulsory Typhoid Vaccination.—Dr. Max Goltman, health commissioner of Memphis, issued an order, September 11, directing that all health department employees under 45 years of age, be vaccinated, as a preventive against typhoid fever.

Personal.—Dr. William Likley Simpson, Memphis, has gone to Europe.——Dr. John Black Steele, assistant city physician of Chattanooga, has been elected city physician, vice Dr. Philander D. Sims, resigned, to accept the position of physician in charge of [illegible] under the joint board of health of the [illegible] and Hamilton County.——Dr. Ruel E. [illegible] physical director of the Memphis Y. M. C. A., has retired.

TEXAS

Personal.—Twenty members of the Dallas County Medical Society attended a banquet, September 2, in honor of Drs. Thomas B. Fisher and Albert W. Nash, the retiring and incoming health officers, respectively, of the city. Dr. James M. Martin acted as toast-master. Dr. Nash entered on his duty as health officer, September 1.——Dr. Adam J. Beall, San Marcos, physician of Hays County, was thrown from his buggy recently, fracturing his clavicle.——Dr. John D. Mitchell, Fort Worth, fractured a rib, August 30, in a violent sneeze.

VIRGINIA

Personal.—Dr. L. W. White has been elected city physician of Suffolk.——The friends of Dr. Charles V. Carrington, Richmond, physician at the state penitentiary for the last twelve years, are making a strong campaign for his reappointment.——Dr. J. Milbourne Daugherty, Nicklesville, has been reinstated as postmaster.

Physicians Register.—The State Department of Health in its bulletin for September, issued a complete register of the physicians practising in Virginia, by districts, counties and cities; and also gave a list of the county boards of health appointed by the State Board of Health, on July 11 of this year. The value of the register would be greatly increased if an alphabetical list had been appended.

GENERAL NEWS

Southern Medical Association Meeting.—The Southern Medical Association will hold its annual meeting in Hattiesburg, Miss., November 16-18.

Clinicians to Meet.—The second annual meeting of the clinical Congress of Surgeons of North America will be held in Philadelphia, November 7-16. Literary sessions will be held every evening and clinical programs will be conducted throughout the day at the various hospitals in the city.

Societies to Meet.—Among coming society meetings in October are the following:

American Association of Railway Surgeons, Chicago, Oct. 18-20.
Delaware State Medical Society, Lewes, Oct. 10.
Idaho State Med [illegible], Oct. 11-13.
Kentucky State [illegible] aducah, Oct. 24-26.
Medical Assn.. o [illegible] homa City, Okla., Oct. 10-12.
Medical Society [illegible] Oct. 24-27.
Minnesota State [illegible] St. Paul, Oct. 5-6.
Mississippi Valley Medical Association, Nashville, Tenn., Oct. 17-19.
Nevada State Medical Association, Reno, Oct. 10-12.
Utah State Medical Association, Salt Lake City, Oct. 4-5.
Vermont State Medical Society, Burlington, Oct. 12-13.

Military Surgeons Elected.—At the twentieth annual meeting of the Association of Military Surgeons of the United States, held in Milwaukee, September 26-29, the following officers were elected: president, Surgeon Charles P. Wertenbaker, United States Public Health and Marine-Hospital Service; vice-presidents, Surgeon W. C. Braisted, U. S. Navy, Brigadier-General Charles Adams, Surgeon-General of Illinois, and Colonel Jefferson Randolph Kean, Medical Corps, U. S. Army; treasurer, Major Herbert A. Arnold, N. G. Penn. (reelected). Baltimore was selected as the next place of meeting.

Sprague Mercantile Agency.—In the past four or five years The Journal has received letters from physicians, complaining of the methods of the Sprague Mercantile Agency, Chicago. The general opinion seems to be that the membership fee which this concern exacts is the most important part of the contract—to the agency. A physician wrote recently, stating that while this collection agency had had his money for thirteen months it had not collected a dollar. This complaint is typical of others that have been received. The Journal would like to hear from other physicians who have had any experience with the Sprague Mercantile Agency.

American Hospital Association.—This organization held its thirteenth annual meeting in New York City, September 19-22. The opening address was made by Mr. George McAneny, president of the Borough of Manhattan who took the occasion to criticize the divided system of hospital supervision existing at present in New York and to recommend greater centralization. Dr. Abraham Flexner made an address on the relation of the hospital to the medical school and suggested questions which he thought hospital managers ought to ask medical schools which sought clinical facilities in their wards. In addition to the scientific work there were several exhibits of interest, in one of which, called the "Chamber of Horrors," was shown the mistakes of nurses and a list of "dont's" for future guidance. Another exhibit was one of occupations for convalescing patients of all ages and still another demonstrated a plan of social service work for the purpose of helping those too well to remain in hospitals and too sick to go back to active labor. The visiting physicians spent considerable time in inspecting the hospitals in this city and the opinion was expressed that hospital conditions here were better than in Canada or Great Britain.

FOREIGN NEWS

The Next International Congress of Gynecology and Obstetrics.—At the Fifth International Congress, which met at St. Petersburg last year, Berlin was selected as the place for the next congress, in 1912, and the date has been definitely fixed as May 29 to 31. Prof. E. Bumm was appointed president; he is at the head of the committee of organization, composed of Profs. Döderlein and A Martin of Germany, D. von Ott of Russia and Mangiagalli of Italy. The general secretary is Dr. E. Martin, 18 Artilleriestrasse, Berlin. The chief topic to be discussed is "Peritonization."

Festschrift for Hansen.—G. A. Hansen, president of the permanent international committee on leprosy, was one of the founders of the *Medicinsk Revue* in Norway in 1884. On the occasion of his 70th birthday recently, the *Revue* issued a special *Festschrift* number in his honor with fifteen able articles on various live topics, especially leprosy and pellagra, all by Norwegian writers. Laache reports a case of sudden death from asphyxia after a mere exploratory puncture, and Holst discusses the scorbutic symptoms observed in pellagra. Each article is accompanied by an abstract in German.

LONDON LETTER

(From Our Regular Correspondent)

London, Sept. 16, 1911.

Motor Noises at Night

The nuisance from the noises made by motor cars has become intolerable. Human ingenuity has exhausted itself in devising apparatus for the emission of all sorts of unearthly noises far in excess of what is necessary to prevent accidents. Some drivers employ the device known as the "cut out" which makes a continuous and harassing noise. Others use electric devices for intensifying the notes of their horns. Others use a siren or multiple horn making distracting, irregular noises. In certain parts of London the night is made hideous by the Babel, rendering sleep difficult or impossible. In a letter to the *Times* an eminent surgeon, Sir Henry Morris, points out the evil results on himself and other residents in the West End. After the lull which midnight brings and after an hour or so of sleep one is aroused in the early morning by the fearsome sounds of the motor horn. "They strike the ear," he says, "bruise the brain, much as a hot and vivid flash of light affects the eye, or the plunge of a knife hurts the flesh." A bill has been introduced into parliament to amend the law in respect to the warning instruments on motor cars. With the concurrence of the local government board, the commissioner of the Metropolitan Police has issued a circular pointing out that while drivers are bound to give audible warning with a view to preventing accidents, they go far beyond this and at night in streets where there is no hidden danger, and the only danger is reckless speed; they endeavor to prevent the possible consequences of this by continuously and obnoxiously sounding their horns, disturbing the rest of residents. Unless some alteration is brought about by motorists of their own impulse he warns them that repressive legislation will be introduced.

MEDICAL NEWS

PARIS LETTER

(From Our Regular Correspondent)

PARIS, Sept. 1, 1911.

Aid for the Blind

Books with raised letters used by the blind are generally very expensive. They have, up to the present time, been of two distinct types: (1) those which were stereotyped, the manufacturing process being so expensive that frequent printing of new books is made almost impossible; (2) those written by hand by some blind person whose good will does not prevent him from making frequent inaccuracies, and who can make but one copy at a time, and that only slowly. Now, as I have indicated in a preceding article in THE JOURNAL (Sept. 17, 1911, p. 1036), M. Ernest Vaughan, the director of hospice des Quinze-Vingts, has devised a press for printing books for the blind by means of which a text of irreproachable exactness can be obtained, and at a cost much less than that of either the stereotyped or the hand-written books. To place this system on the market, he has founded the Société philanthropique d'impressions pour les aveugles, of which the celebrated writer, Anatole France, member of the Académie Française, is president.

What this society proposes to do is this: (1) to provide the blind workers with books on technical subjects—necessary information in the following of their professions—catalogues, references and all the practical information which will enable them to fill positions commanding salaries as large as those drawn by workers who have the use of their eyesight; (2) to establish free district libraries where the blind people can find the means of educating or amusing themselves, in the same way that those who can see may do; (3) to publish and sell books and music for the use of the blind, at the most moderate prices; (4) to give advice to any of them, and particularly to the workers, who will find them willing to give any help which they may need—except money aid, which they make it a practice never to give; (5) and lastly, to propagate M. Vaughan's method, or any other similar method, for printing books for the blind.

The first effort of the society will expend itself on the printing of technical books, which will be sold at a minimum price, or even furnished gratuitously to the extremely poor persons, as the resources of the society permit.

As soon as the number of subscriptions warrant it, centers will be established in the provinces to attract future libraries there. At Marseilles, Dijon, Lyons, Tours, Arras and Lille groups of people are offering quarters and the necessary personnel. The committee of patronage, which is disinterestedly devoting itself to launching the Société philanthropique d'impressions pour les aveugles combines many personalities and different philosophic and political opinions.

The Druggist's Bottle as Agent of Contagion

In most French pharmacies one can return, for a cent or two, bottles, jars and other receptacles. The chances of infection are easy to calculate. Inasmuch as the druggists are not obliged to sterilize the returned receptacles, the only practical means of remedying the evil would be in the refusal of the druggist to take back used bottles. Unfortunately, the druggist does not dare to do this, for the customers, to gain a few pennies, will go to some other druggist. In certain towns, as *La Pharmacie Française* informs us, the druggists have agreed to refuse the return of bottles altogether. A propaganda is now being carried on to have druggists and the public everywhere renounce the practice in question.

A New Responsibility for Physicians

It happens all the time that the country doctor is asked by his patients to bring in his carriage the messenger, who has, in order to gain a little time which may be very precious, come to town after him. The doctor rarely refuses to render such a service. Now it follows, according to several recent decisions, that by so doing he assumes responsibility for the safety of his companion during the trip, and that if an accident occurs in which the latter is injured, the doctor is obliged to bear the consequences.

The Death of Dr. Bruandet

Word has been received of the death of Dr. Louis Bruandet, professor of anatomy at the medical school at Reims. Dr. Bruandet, who was 35 years old, was a victim of his professional duty. Shortly before he left for his vacation, he attended a patient suffering from malignant anthrax, contracted the disease himself, and died soon afterward.

Sources of Cholera

At the last meeting of the permanent commission of the superior counsel of hygiene, Dr. Calmette read his report on the sanitary situation in the city of Marseilles. The result of his investigation was that the origin of the cases of cholera observed in this city, is to be traced not to the water or to the milk, but to shellfish, either those imported from the neighboring towns themselves contaminated, or those gathered on the rivers, in streams or in falls. These shellfish, which are eaten raw, are often filled with vibrios. This explains the isolated cases of cholera which attack an individual or a single family in a certain district. Dr. Calmette demands laws in Marseilles and all along the Mediterranean coast, prohibiting the gathering, sale or importation of shellfish.

The Country Neurasthenic

Dr. Raymond Belbèze, a physician in one of the provinces, who has for some years made a study of several communes in the department of Tarn-et-Garonne, has just published a little book under the title "The Country Neurasthenic," which shows that in this particular district, 30 per cent. of the peasants are subject to neurasthenia, and that this percentage increases yearly. According to Dr. Belbèze, the depopulation, which is particularly rapid in Tarn-et-Garonne (having amounted to 40,000 between 1842 and 1899) is closely related to the increase of neurasthenia there and is explained, among other reasons, by a morbid fear of family responsibility; the numerous and early marriages being almost without exception voluntarily sterile after the birth of the first child. Dr. Belbèze considers that in addition to the economic factor (Tarn-et-Garonne has become greatly impoverished during the last few years) and the social factor (the enervating effect of academic and domestic education) the causes of this neurasthenia are to be found in the prevalence of overwork, inadequat nourishment, and above all in the close blood relationshi which exists between the people, for the inhabitants have inte married for more than a century.

The Public First-Aid Service of Paris

Professor Thoinot has just published his report for tne year 1910 of the public first-aid service of Paris, of which he is the director. It is organized to render aid in various public places and on occasions of public gatherings, in cases of illness, accident, confinement, drowning and violent and natural deaths. Professor Thoinot reports that in the course of 1910, the public service department aided 1,670 people, of which number 321 were submerged, as compared with 1,526, of which 352 were submerged, in 1909. Of these 321 submerged persons (242 men and 79 women) 132 were suicides; 154 were suicides in 1909. Of these 232 remained under the water less than one minute; 33, two minutes; 27, from three to five minutes; 4, from six to ten minutes; and three more than ten minutes. The last three could not be resuscitated. In the stations of aid in the mayor's offices, 268 wounded and 12 sick people were cared for. Stretchers from the different posts have been used to carry those injured in the public streets to the morgue, to the hospital, or to their homes. The organization looked after 50 sick and 12 wounded at the carnival, 50 wounded and 70 sick at the national fête, July 14.

BERLIN LETTER

(From Our Regular Correspondent)

BERLIN, Sept. 7, 1911.

Personals

On the occasion of the centennial jubilee of its foundation, which was celebrated, September 2, the medical faculty of Christiana, gave the honorary title of doctor to Professor Rubner, Professor Rabl of Leipsic and Professor v. Strümpel of Leipsic.

A new chair has been established at Tübingen for skin and venereal diseases and Professor Linser has been appointed the incumbent.

The Distribution of Persons Engaged in the Treatment or Care of Disease in the German Empire

In accordance with a resolution of the federal council (*Bundesrat*) in 1909, an investigation as to the distribution of persons engaged in the treatment of disease, of pharmacies and of persons engaged in pharmacy and nursing in the German empire, was undertaken May 1, 1909. From the results just published by the imperial health office, the following state-

Personal.—The following physicians have returned from Europe: Drs. William M. L. Coplin, George Strawbridge, William L. Rodman, James E. Talley, Thomas A. Cope, J. William White and Dr. and Mrs. J. Cardeen Cooper.——Dr. Francis R. Packard was recently elected president of the Board of Medical Examiners, vice Dr. Henry Beates, Jr., resigned.

TENNESSEE

Compulsory Typhoid Vaccination.—Dr. Max Goltman, health commissioner of Memphis, issued an order, September 11, directing that all health department employees under 45 years of age, be vaccinated, as a preventive against typhoid fever.

Personal.—Dr. William Likley Simpson, Memphis, has gone to Europe.——Dr. John Black Steele, assistant city physician of Chattanooga, has been elected city physician, vice Dr. Philander D. Sims, resigned, to accept the position of physician in charge of [illegible] under the joint board of health of the [illegible] and Hamilton County.——Dr. Ruel E. The visiting physicians spent considerable time in inspecting the hospitals in this city and the opinion was expressed that hospital conditions here were better than in Canada or Great Britain.

FOREIGN NEWS

The Next International Congress of Gynecology and Obstetrics.—At the Fifth International Congress, which met at St. Petersburg last year, Berlin was selected as the place for the next congress, in 1912, and the date has been definitely fixed as May 29 to 31. Prof. E. Bumm was appointed president; he is at the head of the committee of organization, composed of Profs. Döderlein and A Martin of Germany, D. von Ott of Russia and Mangiagalli of Italy. The general secretary is Dr. E. Martin, 18 Artilleriestrasse, Berlin. The chief topic to be discussed is "Peritonization."

Festschrift for Hansen.—G. A. Hansen, president of the permanent international committee on leprosy, was one of the founders of the *Medicinsk Revue* in Norway in 1884. On the occasion of his 70th birthday recently, the *Revue* issued a special *Festschrift* number in his honor with fifteen able articles on various live topics, especially leprosy and pellagra, all by Norwegian writers. Laache reports a case of sudden death from asphyxia after a mere exploratory puncture, and Holst discusses the scorbutic symptoms observed in pellagra. Each article is accompanied by an abstract in German.

LONDON LETTER

(From Our Regular Correspondent)

LONDON, Sept. 16, 1911.

Motor Noises at Night

The nuisance from the noises made by motor cars has become intolerable. Human ingenuity has exhausted itself in devising apparatus for the emission of all sorts of unearthly noises far in excess of what is necessary to prevent accidents. Some drivers employ the device known as the "cut out" which makes a continuous and harassing noise. Others use electric devices for intensifying the notes of their horns. Others use a siren or multiple horn making distracting, irregular noises. In certain parts of London the night is made hideous by the Babel, rendering sleep difficult or impossible. In a letter to the *Times* an eminent surgeon, Sir Henry Morris, points out the evil results on himself and other residents in the West End. After the lull which midnight brings and after an hour or so of sleep one is aroused in the early morning by the fearsome sounds of the motor horn. "They strike the ear," he says, "bruise the brain, much as a hot and vivid flash of light affects the eye, or the plunge of a knife hurts the flesh." A bill has been introduced into parliament to amend the law in respect to the warning instruments on motor cars. With the concurrence of the local government board, the commissioner of the Metropolitan Police has issued a circular pointing out that while drivers are bound to give audible warning with a view to preventing accidents, they go far beyond this and at night in streets where there is no hidden danger, and the only danger is reckless speed; they endeavor to prevent the possible consequences of this by continuously and obnoxiously sounding their horns, disturbing the rest of residents. Unless some alteration is brought about by motorists of their own impulse he warns them that repressive legislation will be introduced.

MEDICAL NEWS

PARIS LETTER

(*From Our Regular Correspondent*)

PARIS, Sept. 1, 1911.

Aid for the Blind

Books with raised letters used by the blind are generally very expensive. They have, up to the present time, been of two distinct types: (1) those which were stereotyped, the manufacturing process being so expensive that frequent printing of new books is made almost impossible; (2) those written by hand by some blind person whose good will does not prevent him from making frequent inaccuracies, and who can make but one copy at a time, and that only slowly. Now, as I have indicated in a preceding article in THE JOURNAL (Sept. 17, 1911, p. 1036), M. Ernest Vaughan, the director of hospice des Quinze-Vingts, has devised a press for printing books for the blind by means of which a text of irreproachable exactness can be obtained, and at a cost much less than that of either the stereotyped or the hand-written books. To place this system on the market, he has founded the Société philanthropique d'impressions pour les aveugles, of which the celebrated writer, Anatole France, member of the Académie Française, is president.

What this society proposes to do is this: (1) to provide the blind workers with books on technical subjects—necessary information in the following of their professions—catalogues, references and all the practical information which will enable them to fill positions commanding salaries as large as those drawn by workers who have the use of their eyesight; (2) to establish free district libraries where the blind people can find the means of educating or amusing themselves, in the same way that those who can see may do; (3) to publish and sell books and music for the use of the blind, at the most moderate prices; (4) to give advice to any of them, and particularly to the workers, who will find them willing to give any help which they may need—except money aid, which they make it a practice never to give; (5) and lastly, to propagate M. Vaughan's method, or any other similar method, for printing books for the blind.

The first effort of the society will expend itself on the printing of technical books, which will be sold at a minimum price, or even furnished gratuitously to the extremely poor persons, as the resources of the society permit.

As soon as the number of subscriptions warrant it, centers will be established in the provinces to attract future libraries there. At Marseilles, Dijon, Lyons, Tours, Arras and Lille groups of people are offering quarters and the necessary personnel. The committee of patronage, which is disinterestedly devoting itself to launching the Société philanthropique d'impressions pour les aveugles combines many personalities and different philosophic and political opinions.

The Druggist's Bottle as Agent of Contagion

In most French pharmacies one can return, for a cent or two, bottles, jars and other receptacles. The chances of infection are easy to calculate. Inasmuch as the druggists are not obliged to sterilize the returned receptacles, the only practical means of remedying the evil would be in the refusal of the druggist to take back used bottles. Unfortunately, the druggist does not dare to do this, for the customers, to gain a few pennies, will go to some other druggist. In certain towns, as *La Pharmacie Française* informs us, the druggists have agreed to refuse the return of bottles altogether. A propaganda is now being carried on to have druggists and the public everywhere renounce the practice in question.

A New Responsibility for Physicians

It happens all the time that the country doctor is asked by his patients to bring in his carriage the messenger, who has, in order to gain a little time which may be very precious, come to town after him. The doctor rarely refuses to render such a service. Now it follows, according to several recent decisions, that by so doing he assumes responsibility for the safety of his companion during the trip, and that if an accident occurs in which the latter is injured, the doctor is obliged to bear the consequences.

The Death of Dr. Bruandet

Word has been received of the death of Dr. Louis Bruandet, professor of anatomy at the medical school at Reims. Dr. Bruandet, who was 35 years old, was a victim of his professional duty. Shortly before he left for his vacation, he attended a patient suffering from malignant anthrax, contracted the disease himself, and died soon afterward.

Sources of Cholera

At the last meeting of the permanent commission of the superior counsel of hygiene, Dr. Calmette read his report on the sanitary situation in the city of Marseilles. The result of his investigation was that the origin of the cases of cholera observed in this city, is to be traced not to the water or to the milk, but to shellfish, either those imported from the neighboring towns themselves contaminated, or those gathered on the rivers, in streams or in falls. These shellfish, which are eaten raw, are often filled with vibrios. This explains the isolated cases of cholera which attack an individual or a single family in a certain district. Dr. Calmette demands laws in Marseilles and all along the Mediterranean coast, prohibiting the gathering, sale or importation of shellfish.

The Country Neurasthenic

Dr. Raymond Belbèze, a physician in one of the provinces, who has for some years made a study of several communes in the department of Tarn-et-Garonne, has just published a little book under the title "The Country Neurasthenic," which shows that in this particular district, 30 per cent. of the peasants are subject to neurasthenia, and that this percentage increases yearly. According to Dr. Belbèze, the depopulation, which is particularly rapid in Tarn-et-Garonne (having amounted to 40,000 between 1842 and 1899) is closely related to the increase of neurasthenia there and is explained, among other reasons, by a morbid fear of family responsibility; the numerous and early marriages being almost without exception voluntarily sterile after the birth of the first child. Dr. Belbèze considers that in addition to the economic factor (Tarn-et-Garonne has become greatly impoverished during the last few years) and the social factor (the enervating effect of academic and domestic education) the causes of this neurasthenia are to be found in the prevalence of overwork, inadequate nourishment, and above all in the close blood relationship which exists between the people, for the inhabitants have intermarried for more than a century.

The Public First-Aid Service of Paris

Professor Thoinot has just published his report for tne year 1910 of the public first-aid service of Paris, of which he is the director. It is organized to render aid in various public places and on occasions of public gatherings, in cases of illness, accident, confinement, drowning and violent and natural deaths. Professor Thoinot reports that in the course of 1910, the public service department aided 1,670 people, of which number 321 were submerged, as compared with 1,526, of which 352 were submerged, in 1909. Of these 321 submerged persons (242 men and 79 women) 132 were suicides; 154 were suicides in 1909. Of these 232 remained under the water less than one minute; 33, two minutes; 27, from three to five minutes; 4, from six to ten minutes; and three more than ten minutes. The last three could not be resuscitated. In the stations of aid in the mayor's offices, 268 wounded and 12 sick people were cared for. Stretchers from the different posts have been used to carry those injured in the public streets to the morgue, to the hospital, or to their homes. The organization looked after 50 sick and 12 wounded at the carnival, 50 wounded and 70 sick at the national fête, July 14.

BERLIN LETTER

(*From Our Regular Correspondent*)

BERLIN, Sept. 7, 1911.

Personals

On the occasion of the centennial jubilee of its foundation, which was celebrated, September 2, the medical faculty of Christiana, gave the honorary title of doctor to Professor Rubner, Professor Rabl of Leipsic and Professor v. Strümpel of Leipsic.

A new chair has been established at Tübingen for skin and venereal diseases and Professor Linser has been appointed the incumbent.

The Distribution of Persons Engaged in the Treatment or Care of Disease in the German Empire

In accordance with a resolution of the federal council (*Bundesrat*) in 1909, an investigation as to the distribution of persons engaged in the treatment of disease, of pharmacies and of persons engaged in pharmacy and nursing in the German empire, was undertaken May 1, 1909. From the results just published by the imperial health office, the following statements are taken: The number of licensed physicians of the German empire has increased by 23.59 per cent. since 1898, the total now being 30,558. The number of physicians connected with institutions has increased at the rate of 60.1 per cent. in contrast with the percentage increase of 20.28 among physicians who do private practice. The large cities show the greatest increase, while in the relatively smallest communities a retrogression can be shown. Generally the public in large cities is four times as richly supplied with physicians as the people of the smallest communities.

The number of professional nurses has nearly doubled in the last eleven years, reaching the number of 68,818. They are classified as domestic (20,026) and institutional (48,792), also as recognized by the state (23,681) and not recognized by the state (45,075), and finally into association nurses and others. The relatively greater participation of the male sex in the entire increase among nurses is not to be denied. The Roman and evangelical sisterhood nurses form respectively 48.3 and 29.2 per cent. of the association nurses.

The persons engaged in the professional treatment of the sick who are not licensed, are equal in number to 17.1 per cent. of the number of physicians in private practice. Altogether they number 4,468, and since 1887 have experienced an increase of 160.8 per cent. and the non-licensed medical women have increased to the extent of 333.4 per cent., as contrasted with the non-licensed men who have increased by 123.4 per cent. The group of midwives has receded in proportion to the population from 7.72 in 1876 to 5.94 per 1,000; this corresponds with the decrease in the birth-rate. The licensed veterinary surgeons have increased since 1887 from 3,113 to 3,813, and 69.7 per cent. of all veterinary surgeons are engaged in the official inspection of cattle and meat.

With reference to pharmacists, the statistics show that a relative decrease has occurred, for in 1895 there were 0.99 pharmacists for every 10,000 inhabitants, in 1909, 0.97.

Cerebrospinal Meningitis in Prussia in 1910

In 1910 there were officially reported 369 cases of cerebrospinal meningitis as opposed to 1,030 in the year 1909. Of these thirty-seven cases were shown to belong to other diseases of the brain and in twenty-four cases the diagnosis was doubtful. Most of the cases occurred, as in the previous year, in the provinces of Düsseldorf, Arnsberg and Oppein. According to season, the largest number of cases occurred, as in the previous year, in spring and winter; 60 per cent. were of the male sex, showing again a preponderance over the females. As to the age they were generally children from 6 to 10 years. Of the patients 136 had recovered at the end of 1910 and 194, or about 60 per cent., had died. Death occurred most frequently in the first week, namely, in seventy-two cases. Of 136 who recovered, so far as facts are available, only two cases of permanent injury to health remained, namely, deafness. The diagnosis was generally confirmed by bacteriologic examination. According to the reports, forty-one patients had been treated with meningitis serum; of these twenty-three recovered and twelve died.

Reduction of the Excess of Females in Prussia

In almost all European countries the female sex has for a long time outnumbered the male; only in the East do the men exceed the women in number. This has been numerically determined in Roumania, Servia, Bulgaria and Greece. In Turkey the sexes are not separated in the census, but it is certain that there also the male sex is predominant. The reason for this difference is partly to be found in the greater tendency of men to shift about from place to place. Only when exact facts are obtainable with reference to the sex at birth can it be determined how far the greater or less neglect of one or other sex, especially during the period of infancy, is responsible for the varying distribution. In Germany there are annually about 60,000 more boys born than girls. In spite of this, for various reasons, the female sex outnumbers the male to a marked degree. But there is one peculiar fact, namely, that in the last census period, the excess of females over males in Germany has diminished. If this ratio continues, in thirty years or less the sexes will be equal in numbers. At present there are for each 1,000 persons, 506 women and 494 men. If it is assumed that there is a general variation in favor of the male sex, it may be explained by a lesser tendency of the men nowadays to emigrate, and by the number of persons who have moved to Prussia from elsewhere in the empire. Still another factor is the gratifying lowering of the infant death-rate, to which the male sex, in consequence of its larger proportion, contributes to a greater extent than the female.

VIENNA LETTER

(From Our Regular Correspondent)

VIENNA, Sept. 23, 1911.

A Technical Museum with a Medical Department

Some time ago a private committee organized to erect in Vienna a permanent technical museum. The government not only granted a large sum of money but also caused the technical schools to donate appropriate subjects to the museum. One of the divisions will be devoted to public health, medicine in general, and sanitation, and men of the profession all over the world are invited to contribute any object they might think of value for this institution. A museum of this kind will undoubtedly be equally interesting to the general practitioner, the medical student and the public health official. The committee has already been offered a number of old medical instruments, mixtures, laboratory and pharmacy outfits, including a handsome collection of quack remedies, the compositions of which are analyzed and exhibited. The sanitary exhibit will include the technical details of pure food- and water-supplies, methods and apparatus for the removal of town garbage and waste, filtering-beds and smoke-abating contrivances, and also apparatus and outfits for first aid to the injured, especially in the case of railway accidents, coal-mine explosions, and injuries received in war. The cooperation of medical experts will ensure a proper selection of the exhibits offered.

Protection of Laborers in the Sugar Factories and the Printing Trade

Two ordinances of the ministry of public works, dealing with the conditions in the sugar industry and the printing trade, have an important bearing on the health of a large percentage of the laboring class. These regulations are the outcome of inquiries by a special accident commission and are in strict harmony with the special progress of work in the two mentioned lines of industry. In the sugar industries, precautions to be taken and means necessary for prevention of scalding, cauterizing, poisoning or producing of dangerous dust are enumerated. A periodic regular examination of apparatus which are deemed especially dangerous (recipients, centrifuges, etc.), is made compulsory, and hygienic precautions for the protection of the consumers of the sugar are also added. The regulations concerning the printing trade are directed chiefly against the dangers of lead-poisoning. Thus the minimum of volume of air per laborer has been fixed proportionally with the richness in lead dust in the various industries; proper ventilation is made compulsory. The walls and floors of the workshops must be cleaned at least twice a week and subterranean work-rooms are not allowed at all where lead is used. Female and juvenile workers may not be employed for certain kinds of labor involving great exposure to the risk of lead-poisoning. Colors containing lead must be stated as such and strict observation of the prohibition of eating, drinking and smoking while at work is rigidly enforced. One provision is that the workers in industries using lead shall be examined periodically by public health officers who will be empowered to order a person to stay away from work if found to be affected by plumbism. The readmission of such persons will be conditional on producing a certificate of health. The regulations will go into force Jan. 1, 1912, in the existing factories, and at once in those which will be erected between now and that date.

A Supply of Serum Against Serpents for the Austrian Army

The two army corps stationed in the southern districts of the empire have been provided for some time with a large amount of antitoxic serum for use in cases of soldiers being injured by serpents. The excessive heat and dryness of the temperature has caused a large increase of these inhabitants of the rocky and dry districts and especially the viper has appeared in numbers not seen before. Acting on a suggestion of the head of the army medical corps, the serum was obtained in a sufficient quantity to supply all staff hospitals in the area in question, and the regimental surgeons have received careful instructions how and when to use it. It was also necessary to provide a number of syringes required for the use of this serum. Every year a few cases of fatal injuries by vipers have been reported, mostly from the civilian population. The application of permanganate of potash in crystals to the wound was not always successful, and so the more modern method has been recommended and it will be available both for the military and civilian patients requiring it.

Miscellany

"An Example to Follow.—It is evident that the state of Louisiana has at the head of its board of health a man of unusual enterprise and originality, Dr. Oscar Dowling. He has rightly been described as not only a man of ideas, but a man of action. Reports of what President Dowling has done in and out of Louisiana show that not only has he enforced sanitation and laws of healthful living, but that he has taught their principles in an efficient and novel way. The best example of this is his famous health train, which traveled nearly seven thousand miles and visited over two hundred and fifty towns and cities in the state. Over one hundred and fifty thousand people along the line of this route visited the laboratory exhibits on the train and saw the moving-picture lectures. This educational work was so successful and valuable that Dr. Dowling took the traveling exhibit to the. . . [American Medical Association] convention at Los Angeles. . . and returned across many states, offering everywhere a demonstration of the causes and methods of cure for disease. One car had an additional exhibit showing the methods of preventing disease; a second taught how food should be prepared and guarded; a third was for the accommodation of Dr. Dowling and his assistants. The plan, in *Louisiana at least, included not only education but inspection*, as is shown by the following extract from a newspaper account:

> "On the arrival of the train at a town, the doctor was off on his tour of inspection—a thing little known before his arrival. Without fear or favor he inspected everything, the water-supply, the treatment of sewage and the disposal of garbage, the slaughter-houses, the markets, the bakeries, the hotels, the restaurants, the schools, the jails, the sanatoria, the railroad stations; and without fear or favor he reported on them all.

"Twenty years ago such an effort to bring about right health conditions was unheard of, and any one who proposed it might have been laughed at as a dreamy theorist."—*Outlook*, Sept. 23, 1911.

Suggestions in Science.—Because every discovery becomes the basis for further study, the imagination of the investigator *is constantly stimulated. New facts suggest in turn* other facts and point to unsuspected relations between things that have long been known. Bayliss and Starling's discovery of a natural chemical stimulant which induces secretion of the pancreas led directly to the explanation of continued gastric secretion, and also to finding the marvelous mechanism by which the mammary glands are prepared for the giving of milk. Thus, though the interests of the man of science seem at the moment narrow and restricted, they may nevertheless lead his thought out into many diverse realms of knowledge. These excursions of the imagination offer repeated suggestions for fresh adventure. The look, therefore, is always forward to what may be seen when the next step is taken. Seeking new things becomes in time a fixed habit. Past achievements neither satisfy interest nor hold attention—they become fused with the established routine from which it is happiness to escape. The chance of beholding unsuspected wonders, or the possibility of finding that something imagined is really true is a constant incitement to further search and furnishes the zest and interest which are among the best rewards of the investigator.—Cannon in *Science*.

Roentgen-Ray Treatment of Lymphadenoma.—The x-rays produce a rapid diminution in the size of the glands, and it is said that life is thus prolonged. X-rays destroy the lymphoid tissue, but leave the fibrous tissue unaffected. It must be borne in mind that by free application of x-rays the lymphocytes and the healthy lymphoid tissues may be too extensively destroyed and that harm may thus be done. It has been noted that in some instances although rapid diminution in size follows x-ray treatment the glandular enlargement returns very rapidly when the treatment is stopped. It appears that treatment by radium would be difficult from the large amount of radium which would be required to deal with the extensive lesions.—H. D. Rolleston, in the *Practitioner*.

Marriages

HOWARD CHARLES RANDOLPH, M.D., Aberdeen, Wash., to Miss Lillian Elizabeth Burke of Ann Arbor, Mich., at Seattle, September 11.

WILLIAM C. GIBSON, M.D., Empire, C. Z., to Miss Edith M. Seymour of Petoskey, Mich., at Cristobal, C. Z., August 31.

HOWARD BULKELEY HAYLETT, M.D., Hartford, Conn., to Miss Hortense Idell Dunham of Burlington, Vt., August 31.

ARTHUR M. BISHOP, M.D., Chicago, to Mrs. Della Robbins Burnett of Good Hope, Ill., at Galesburg, August 26.

HERBERT C. CLARK, M.D., Ancon, C. Z., to Miss Jessie Sanderson of Norfolk County, Va., at Ancon, September 2.

WALDEMAR RUSCHE, M.D., Giessen, Germany, to Miss Louise W. Treide, at Baltimore, September 14.

EARL H. COLEMAN, M.D., Los Celtos, Cal., to Miss Nain Taylor of Curpentino, Cal., September 6.

ALBERT BREWER LANDRUM, M.D., to Miss Flora Esther Rohe, both of Columbus, O., June 12.

JOHN D. MACLEAN, M.D., Greenwood, B.C., to Miss Minnie Watson, at Tara, Ont., recently.

JOHN J. KERWIN, M.D., to Miss Helen Marie White, both of Chicago, September 12.

Deaths

Maurice Dwight Clarke, M.D. Harvard Medical School, 1882; of Haverhill, Mass., a member and once vice-president of the Massachusetts Medical Society; for twenty-two years secretary of the Essex North District Medical Society; formerly a member of the Haverhill (Mass.) Board of Health and a member of the local pension board; formerly consulting physician to the Danvers State Hospital; surgeon and chief of staff of the Hale Hospital, and secretary and treasurer of the Haverhill Medical Club; died in Danvers, Mass., September 7, aged 59.

Granville Wilson Tinkham, M.D. Harvard Medical School, 1871; of Weymouth, Mass.; a member of the Massachusetts Medical Society and once president of the South Norfolk District Medical Society; for several years medical examiner for the coroner of Weymouth district; died in the Boothby Hospital, Boston, September 9, a few days after surgical operation, aged 63.

George D. Crandall (license, Tioga County, Pa., 1881); a member of the American Medical Association, Erie Railroad Surgeons' Association and International Association of Railway Surgeons; surgeon of the Tioga Division of the Erie Railroad; surgeon in charge of the Cottage State Hospital, Blossburg; died at his home in that place, August 22, from appendicitis, aged 67.

Charles Cornelius Payne, M.D. University of Kansas, Kansas City, 1907; a member of the Kansas Medical Society and for a time a lecturer of the faculty of his alma mater; died at the home of his wife's mother in Lawrence, September 14, from the effects of a gunshot wound of the chest, believed to have been self-inflicted with suicidal intent, aged 38.

John Craddock Drennan, M.D. Vanderbilt University of Nashville, Tenn., 1893; state senator from the district made up of Cannon, Rutherford and De Kalb counties; died at his home in Woodbury, Tenn., September 13, from the effects of a gunshot wound, believed to have been self-inflicted with suicidal intent, aged 45.

George William Reynolds, M.D. University of Buffalo (N. Y.), 1880; Rush Medical College, 1897; for many years a member of the American Medical Association; chief of the gynecological staff of St. Joseph Hospital, Chicago; died in that institution, September 9, from chronic interstitial nephritis, aged 57.

Eugene Arthur Hults, M.D. Hahnemann Medical College, Philadelphia, 1886; from 1895 to 1898 health officer of Perth Amboy, N. J., and since May 15, 1911, health officer of the port; died at his home, September 4, from nephritis, aged 50.

Edgar M. Griffith, M.D. Cooper Medical College, San Francisco, 1876; died at his home in Boyle Heights, Los Angeles, September 7, from nephritis, aged 53.

Abraham M. Neyman, M.D. Western Reserve University, Cleveland, O., 1853; a member of the Medical Society of the State of Pennsylvania, and a charter member of the Butler County Medical Society; died at the home of his daughter in Butler, September 16, from senile debility, aged 65.

Elmer Wallace Hamilton, M.D. Jefferson Medical College, 1907; a member of the American Medical Association; of Newtown, Pa.; formerly a member of the staff of the New Jersey State Epileptic Colony, Skillman; died in a hospital in Philadelphia, September 1, aged 32.

Alton D. Du Puy, M.D. University of Louisville (Ky.), 1886; for twenty years a practitioner of San Antonio, Tex.; for twelve years chief surgeon of the International and Great Northern Railroad; died at his home, September 8, from heart disease, aged 48.

D. O. Fruth, M.D. Columbus (O.) Medical College, 1879; of Los Angeles, Cal.; a practitioner of Chicago until 1897, and again from 1903 to 1909; died at the home of his sister near Fostoria, O., September 13, from disease of heart and kidneys, aged 55.

John W. Ballard, M.D. Medical College of Ohio, Cincinnati, 1879; for thirty-five years a practitioner of Logansport, Ind., and for three terms coroner of Cass County; died at his home in Logansport, September 9, from cerebral hemorrhage, aged 56.

Thomas Richard Ward, M.D. State University of Iowa, Iowa City, 1873; Bellevue Hospital Medical College, 1882; surgeon to the Swedish Hospital, Omaha; died suddenly at his home in that city, September 10, from heart disease, aged 64.

Clarence Cullens, M.D. Kentucky School of Medicine, Louisville, 1871; a Confederate veteran; probate judge of New Albany County for one term; died at the home of his sister in Pontotoc, Miss., September 8, from bronchitis, aged 69.

Leonard Chester Backus, M.D. University of Michigan, Ann Arbor, 1887; a member of the Ohio State Medical Association; formerly of Fayette, O.; died at his home in Ann Arbor, Mich., September 8, from ptomain poisoning, aged 50.

J. H. Smith, M.D. Atlanta (Ga.) Medical College, 1877; for several years president of the Iowa Farmers' Insurance Company, Cedar Rapids, with a winter residence in Orlando, Fla.; died at his home in Cedar Rapids, August 30.

Edward Desmond, M.D. Tulane University, New Orleans, 1906; of Spokane; a member of the Washington State Medical Association; died in the Sacred Heart Hospital, Spokane, September 11, from typhoid fever, aged 41.

Elisha Sergeant Athearn, M.D. College of Physicians and Surgeons, Keokuk, Ia., 1865; formerly of Oberlin, Kan., and North English, Ia.; died at his home in Boulder, Colo., September 4, from senile debility, aged 76.

Oliver H. Arnold, M.D. Harvard Medical School, 1867; for a time connected with Brown University, Providence, R. I. in the department of biology and comparative anatomy; died at his home in Providence in June, aged 70.

William Francis Pier, M.D. Bellevue Hospital Medical College, 1878; of Avoca, Pa.; formerly coroner of Luzerne County, and a school director; died at his summer home in Elmhurst, September 5, from diabetes, aged 55.

William Henry Viney (license, Massachusetts, years of practice, 1894); surgeon of New York Volunteers during the Civil War; a Forty-Niner; died at his home in Springfield, Mass., September 8, aged 85.

Walter Sullivan Holladay (license, Marion County, Ala., 1888); for ten years a member of the board of censors of the Marion County Medical Society; died at his home in Hamilton, September 7, aged 59.

Gabriel Miesse, M.D. Eclectic Medical Institute, Cincinnati, 1847; a pioneer practitioner of Lancaster, O.; died at the home of his cousin at Columbus, O., September 11, from heart disease, aged 75.

Robert P. Keesee, M.D. Leonard School of Medicine, Raleigh, N. C., 1901; a member of the National (Colored) Medical Society; died at his home in Annapolis, Md., August 26, from appendicitis, aged 32.

Phoebe E. Harding, M.D. (license, Ohio, years of practice, 1890); for more than forty years a practitioner; died at her home in Marion, O.; May 29, 1910, from cerebral hemorrhage, aged 66

William Nelson Fry, M.D. University of Vermont, Burlington, 1887; a member of the Iowa State Medical Society; died at his home in Marcus, September 12, from cerebral hemorrhage, aged 46.

Andrew Jarritte Pool (licensed, Arkansas, 1903); for thirty-eight years a practitioner of Georgia, Texas and Arkansas; died at his home in Mena, Nov. 30, 1910, from cerebral hemorrhage, aged 59.

William Fritchey Roth, M.D. Hahnemann Medical College, Philadelphia, 1878; of Manheim, Pa.; died in St. Joseph's Hospital, Lancaster, Pa., September 3, from intestinal obstruction, aged 55.

Benjamin W. Stauffer (license, Lebanon County, Pa., 1881); for nearly sixty years a practitioner of Campbelltown; died at his home in that place, September 10, from senile debility, aged 85.

Robert Chambers Moorehead, M.D. Baltimore (Md.) Medical College, 1886; formerly of Washington, Pa.; died suddenly at his home in Pitcairn, September 7, from heart disease, aged 57.

James M. Fry, M.D. Kentucky School of Medicine, Louisville, 1876; a Confederate veteran; died at his home in Wills Point, Tex., September 10, from cerebral hemorrhage, aged 60.

Dugald Leitch McAlpine, M.D. University of Toronto (Ont.), 1863; of Vancouver, B. C.; died in that city, April 24, from the effects of a street car accident four years before, aged 76.

Endyman F. Graham, M.D. University of Tennessee, Nashville, 1891; of Marietta, Okla.; a member of the Oklahoma State Medical Association; died in Chicago, September 5.

Tolman F. Andress, M.D. (license, Kansas, 1901); an eclectic practitioner for forty-three years; died at his home in Liberty, Sept. 10, 1910, from valvular heart disease.

Francis Milton Cragin, M.D. Homeopathic Medical College of Pennsylvania, Philadelphia, 1860; died at his home in Norwood, Mass., in June, from heart disease, aged 77.

John N. Jones, M.D. University of Buffalo (N. Y.), 1898; for two terms coroner of Chemung County, N. Y.; died at his home in Erin, September 5, aged 38.

Eugene F. Rink, M.D. Hahnemann Medical College, Philadelphia, 1877; died at his home in Burlington, N. J., September 6, from heart disease, aged 60.

Archibald A. Strange, M.D. University of Louisville (Ky.), 1889; died recently at his home in Burkesville near Martinsburg, from senile debility, aged 70.

Arnold Carpenter Davis, M.D. Hahnemann Medical College, Chicago, 1881; died at his home in Farina, Ill., Sept. 15, 1910, from acute enteritis, aged 71.

Henry T. Whiting, M.D. Chicago Homeopathic Medical College, 1883; died in his office in Rockford, Ill., September 13, from acute gastritis, aged 73.

Lawson Rosencrans Robinson, M.D. Kansas City (Mo.) Medical College, 1892; of Kansas City; died in Hot Springs, Ark., September 9, aged 49.

Mark W. Allison, M.D. University of Nashville (Tenn.), 1860; died recently at his home near Whitaker, Tex., from nephritis, aged about 75.

Alexander A. Watts, M.D. Savannah (Ga.) Medical College, 1856; died at his home in Montezuma, Ga., in July, from valvular heart disease.

William M. Flowers, M.D. Tulane University, New Orleans, 1880; died at his home in Florence, Miss., September 4, from uremia, aged 55.

George W. Lane, M.D. Atlanta (Ga.) College of Physicians and Surgeons, 1900; died at his home in Helena, Ga., in November, 1910.

John Search Newton, M.D. Jefferson Medical College, 1867; died at his home in Cedarcreek, Ark., in November, 1910, aged 67.

Daniel Stevens, M.D. Bennett Medical College, Chicago, 1878; died at his home in Fairfield, Neb., September 1, aged 74.

John Kubus (license, Pennsylvania, 1908), of Braddock, Pittsburgh; died recently in Kars, Germany, aged 37.

Mason Thomson, M.D. Bellevue Hospital Medical College, 1876; of New York City; died July 6.

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession.

THE BIO-ASSAY OF EPINEPHRIN PREPARATIONS

Report of the Council on Pharmacy and Chemistry

The variable quality of epinephrin preparations having been brought to the attention of the Council on Pharmacy and Chemistry, a committee was appointed to determine means of securing uniformity of composition in these products. In particular the committee was to study the keeping qualities of epinephrin solutions and to propose a uniform method for the valuation of preparations depending for their activity on the blood-pressure-raising principle of the suprarenal gland. The report of this committee was submitted to the Council's Committee on Pharmacology and after discussion was adopted by the Council. Its publication having been authorized, it appears below:

W. A. Puckner, Secretary

The experiments of Reid Hunt, of Sollmann & Brown, and of W. H. Schultz have shown that the various commercial samples of epinephrin solution differ considerably in activity. It may fairly be assumed that these variations are not due to any intentional difference in composition, but may be attributed, in part, to the spontaneous deterioration with age and exposure and in part to different methods employed in standardizing the solutions at the factory.

Deterioration would naturally depend on the preservative used and on the conditions to which the sample has been exposed. Until the influence of these is better known, it would not be fair to set an age limit. It is better to rely on occasional standardization of samples bought in the open market; and it is herewith recommended that arrangements be made to this end. A variation of 15 per cent. from the claimed strength might be permitted without detriment to the public, and with fairness to the manufacturers. It is highly desirable, however, that manufacturers stamp the age of manufacture on the container, to guard against samples which are obviously over-aged.

As regards the method of standardization there seems to be universal agreement that the preference should be given to the blood-pressure method, the principle of which was first published by E. M. Houghton. In order that different observers may obtain uniform results by this method, certain details must be observed rigorously, while others may be left to the discretion of the experienced experimenter—and only such should undertake bio-assays. The subjoined method has been elaborated to unify these essential details.

The question of supplying an absolute standard has not yet been solved. This requires the issuance of an absolutely pure epinephrin, or of samples of known, absolute strength. Until arrangements for this can be made, the results will not be absolute; but the unification of methods is desirable even for comparative experiments.

It is recommended, therefore, that the method about to be described be employed in investigations by the Council, and that it be published for the convenience of other investigators and for the information of the manufacturers; it was further recommended that its use by the latter be left optional at least for the present.

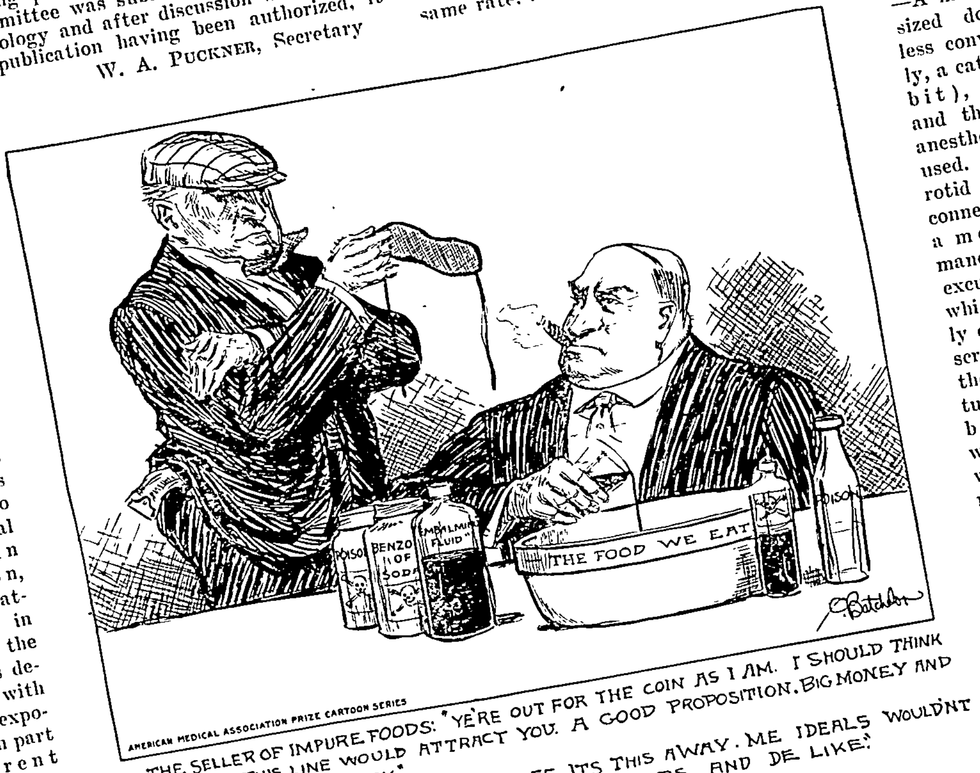
BIO-ASSAY OF EPINEPHRIN PREPARATIONS

The strength of epinephrin preparations is to be stated in terms of pure epinephrin, and must not differ by more than 15 per cent. from the strength as determined by the quantity required to produce the same rise of blood-pressure as is produced by a known quantity of pure epinephrin, when both are injected, in approximately the same dilution, and at the same rate, into an homologous vein of the same mammal.

1. *Preparation of Experiment:*—A medium-sized dog (or less conveniently, a cat or rabbit), weighed and thoroughly anesthetized, is used. The carotid artery is connected with a mercurial manometer, the excursions of which are partly damped by a screw clamp on the connecting tube. It should be made to write on a drum which should revolve slowly—about 1 to 4 inches per minute.

A short cannula of small bore is tied into each saphenous vein close to its junction with the femoral vein and the veins clamped off with small artery clamps. One of these is for the standard solution, the other for the solution to be standardized. These cannulæ are provided with rubber connections so that the dead space between the opening into the vein and that of the standardized 1 c.c. all-glass syringe does not exceed 0.5 c.c. Two all-glass syringes may be used for making the injections, one marked *A* for the standard solution, and the other marked *B* for the solution to be standardized (or graduated burettes may be used). Both vagi are divided and artificial respiration is performed. Care should be used to maintain a uniform anesthesia, complete enough to avoid muscle-movements, throughout the experiment.

2. *Preparation of Solutions:*—The standard solution is prepared by dissolving 1 part of pure epinephrin hydrochlorid in 100,000 parts of 0.9 per cent. sodium chlorid (NaCl) solution.[1]



AMERICAN MEDICAL ASSOCIATION PRIZE CARTOON SERIES

THE SELLER OF IMPURE FOODS: "YE'RE OUT FOR THE COIN AS I AM. I SHOULD THINK THIS LINE WOULD ATTRACT YOU. A GOOD PROPOSITION. BIG MONEY AND LITTLE RISK"
SECOND STORY MAN: "WELL YE SEE ITS THIS AWAY. ME IDEALS WOULDN'T STAND FOR POISONING LITTLE KIDS AND DE LIKE."

---

[1] The Hygienic Laboratory, the U. S. P. Revision Committee, or the Council on Pharmacy and Chemistry should issue a standard trituration of epinephrin hydrochlorid with NaCl 1:900; the standard solution may be prepared by dissolving 0.9 gm. of this in a sufficient quantity of distilled water to make 100 c.c.

The preparation to be standardized is diluted with normal saline solution to approximately the same strength, as nearly as can be estimated, of that of the standard used.

3. *Determination of Standard Dose:*—One of the syringes (*A*) and its cannular connection are filled with the standard 1:100,000 solution. The blood-pressure tracing is started on a slowly revolving drum, and the standard solution is injected in the dose of 0.1 c.c. per kilo of body weight at such a rate that 1 c.c. passes into the vein in five seconds. Soon after the blood-pressure begins to return to normal the drum may be stopped.

The rise of the blood-pressure should be about 25 to 45 mm. of mercury (equivalent to 12.5 to 22.5 mm. rise of the writing point of a U-shaped manometer), and it should be submaximal. To determine the latter, a second injection of 0.15 c.c. per kilo should be made, with tracing, which should show a higher rise.

If the dose of 0.1 c.c. per kilo does not give a submaximal rise of at least 25 mm.; or if it gives a maximal rise, the dose should be increased or reduced respectively, until the standard effect is obtained, and this dose should be considered the "standard dose" for this animal. The injections should be made at the same rate (1 c.c. in five seconds), and an interval of at least three minutes should elapse after the blood-pressure has returned to the normal, before another injection is made.

4. *Adjustment of Dosage of the "Unknown" Solutions:*—The solution of the "unknown" sample is diluted as directed under No. 2. The unused cannula in the saphenous vein and syringe *B* are filled with the solution to be tested. A "standard dose" (see last paragraph of No. 3) is injected at the rate of 1 c.c. in five seconds, and at intervals of from three to five minutes, while a tracing is being taken. The rise of pressure is compared with that produced by the standard dose of the standard solution. According to the result so obtained, the unknown solution is diluted or strengthened, and the results controlled by injections (occasionally making an injection of the standard solution to insure constancy in the reaction of the animal). Final equality is tested by injecting alternately the same dose of the standard and unknown solutions until the average rise from three successive injections is equal within 15 per cent.

5. *Use of Several Animals:*—If an animal reacts abnormally to the standard epinephrin solution, the results from that animal shall be rejected. If the reaction changes during the course of the experiment, or if the blood-pressure falls permanently below 80 mm. of mercury, then the results after this change or fall should be rejected, or at least not compared with those obtained before the changes occurred.

The relation of the unknown solution to the standard solution should be determined on several animals, until the results on three (3) animals agree within 15 per cent., and the average of the three (3) animals shall be accepted as the final result.

Diarrhea in Infants.—The treatment advised by R. Rorke (*Western Canada Medical Journal*) for this condition is exceedingly simple. The bowels are evacuated thoroughly by castor oil if there is serious vomiting, or by lavage of the stomach and calomel in small and repeated doses if there is vomiting of a persistent character. The colon is cleared out by irrigation with normal saline solution introduced high up in the bowel. All food is withdrawn for at least twenty-four hours, giving only sterile water, which may be flavored with a little tea. If the digestive tract continues unsettled, albumin water and strained soups or broths may be given. These latter may also be used as a means of getting back to the breast again, when an abrupt return might bring about a relapse. On doing this a portion of these forms of nourishment or some sterile water should precede the nursing from the breast so as to restrict the amount of milk taken at each feeding. In most of these cases all medicinal treatment is usually unnecessary. However, if the motions become quite watery, fairly large doses of bismuth subnitrate may be prescribed with advantage.

Association News

APPOINTMENTS ON COMMITTEES

Dr. John B. Murphy, president of the American Medical Association, has made the following appointments on committees for 1911-12:

Committee on Transportation and Place of Session

(To complete the Committee, in addition to J. Rawson Pennington, Chairman, elected by the House of Delegates.)

Thomas J. Murray....................Butte, Mont.
William L. Brown....................El Paso, Tex.
James P. Hutchinson....................Philadelphia
William E. Anderson....................Farmville, Va.

Committee on Nomenclature and Classification of Diseases

Alembert W. Brayton....................Indianapolis

(Vice Victor C. Vaughan, resigned.)

Committee on Anesthesia

George Emerson Brewer, Chairman, New York City
Thomas W. Huntington..............San Francisco
Yandell Henderson..............New Haven, Conn.
Fred T. Murphy........................St. Louis
E. Denegre Martin....................New Orleans

Committee on Establishment of Physicians' Sanitarium

Edward Jackson, Chairman....................Denver
Alexander C. Magruder.......Colorado Springs, Colo.
Joseph Yates Porter..............Jacksonville, Fla.
Algernon T. Bristow....................Brooklyn
Fitch C. E. Mattison..................Pasadena, Cal.

Committee to Formulate Amendments to the Constitution and By-Laws to Extend Membership

D. S. Fairchild, Chairman..............Clinton, Ia.
John W. Young....................Grenada, Miss.
Charles S. Sheldon..................Madison, Wis.
Horace D. Arnold........................Boston
Jere L. Crook....................Jackson, Tenn.

Committee to Arrange for Clinic Days

Charles L. Mix, Chairman..................Chicago
Edward Martin....................Philadelphia
Philip Marvel..................Atlantic City, N. J.
Alexander Lambert....................New York
John M. T. Finney....................Baltimore

Committee to Arrange Appropriate Lectures to the Public at the Annual Meetings

William A. Evans, Chairman..............Chicago
Maria M. Vinton..................East Orange, N. J.
Rosalie S. Morton..................New York City
Joseph S. Neff....................Philadelphia
Edward Guion..................Atlantic City, N. J.

Committee to Investigate the Advisability of Publishing a Small Medical Journal

Joseph N. McCormack, Chairman..Bowling Green, Ky.
George A. Moleen........................Denver
Edward E. Dorr....................Des Moines, Ia.
George T. Palmer..................Springfield, Ill.
Park W. Willis....................Seattle, Wash.

Committee to Investigate the Advisability of Publishing a Health Journal

William A. Evans, Chairman..............Chicago
Benjamin R. McClellan....................Xenia, O.
Seale Harris....................Mobile, Ala.
Gardner T. Swarts..................Providence, R. I.
Francis E. Fronczak..................Buffalo, N. Y.

Committee to Conservation Congress

The President has created and appointed the following Committee to Represent the American Medical Association at the Third National Conservation Congress:

William A. Evans, Chairman..............Chicago
Abraham Jacobi....................New York
Hubert Work....................Pueblo, Colo.
Norman Bridge..................Los Angeles, Cal.
Oscar Dowling....................Shreveport, La.
The Very Rev. Andrew Morrissey...South Bend, Ind

Correspondence

Fatal Poisoning from Strychnin in the Nose

To the Editor:—September 6, about 11:00 a. m., a man in the habit of snuffing cocain went to a drug store and called for a bottle of that drug. By mistake he was given a bottle of strychnin sulphate, of which, he said, he used about the amount of a pea before he left the drug store. At noon the same day, I was called to see him and he told me that he had just taken a dose of cocain which was about to kill him; it had never had such effect before. While I was preparing a hypodermic injection, I received a message explaining that the substitution of strychnin for cocain had just been discovered in the drug store. When I returned to the patient, he was having convulsions and continued to have them off and on until he died at 1:30 p. m., about two and a half hours after having used the poison. I do not remember having seen a report of any case of poisoning from strychnin sulphate in this manner, and I would like to have an opinion on it.

J. A. BURNETT, Marble City, Okla.

COMMENT.—Naturally the placing of a soluble salt of strychnin, like the sulphate, in the nasal cavity affords an opportunity for absorption as great as, or greater than, when swallowed. The dose given can be known only approximately, but must have been several times as large as doses which are known to have proved fatal. The fatal period was about the average. The unfortunate character of the accident needs no comment. In the reported human strychnin-poisonings, the poison has been administered by the mouth or hypodermically so far as our observation goes except in two instances: In one case after the application of powdered strychnin to the eye, tetanus followed in three or four minutes (Schuler: *Gaz. méd. de Paris*, 1861, Series 3, xvi, 98). In another instance, the inhalation of steam from a hot mixture containing strychnin caused mild poisoning (Newbecker: THE JOURNAL A. M. A., Jan. 30, 1904, p. 310).

"There's a Reason"

To the Editor:—On my return from an extended trip in the East I was much surprised to learn that THE JOURNAL of the American Medical Association, in its issue of August 19, had taken occasion to attack the *American Journal of Clinical Medicine* editorially.

In this editorial the reader is insidiously led to the conclusion that there was a carefully prepared plan on our part, in cooperation with Mr. Post, to collect testimonials for Grape-Nuts and Postum Cereal. That this inference is unjustified could easily have been learned by THE JOURNAL, if it had taken the trouble to communicate with me. However, I am glad to give the profession all the facts in the case, and these are as follows:

Some months ago I had the pleasure of a personal interview with Mr. Post. At that time I was impressed by his candor and evident essential honesty, and convinced that he had not for some time been receiving fair treatment at the hands of some of his critics. While I believed, and still believe, that he has made a serious mistake in the character of some of his advertising (and this I took occasion to tell him personally—and he admitted it) I was also convinced that he was being made the victim of unnecessarily bitter attacks. While I would not defend him for advertising his foods as "cures" for disease, I did believe and still believe that the foods themselves are good, and that in advocating simplicity in diet and showing the harmfulness of the caffein-bearing beverages, he was rendering a real service to the people.

It was this feeling, with the desire to learn exactly how the readers of our journal felt toward Mr. Post and his products, that led me to send letters (we were quoted in THE JOURNAL correctly) to quite a number of our subscribers, their names being taken at random. I had decided that whether we should continue carrying the advertisement of the Post products or not was to depend on the character of the replies which we received from this straw vote. As a result of this vote it may interest you to know that we have received and have on file, subject to inspection, about 700 letters in praise of these products; about 500 which are noncommittal or indifferent, and about fifty which are condemnatory—but with no essential reasons given. We still carry their copy.

Your inference that the purpose of this campaign was to collect testimonials for Mr. Post was an unfortunate mistake. I am frank to say that a few (a mere bagatelle, proportionately) of these letters received were sent to Mr. Post for his inspection (but in every case with the writer's permission); and so far as we know, not one of these has been published.

I sent out these letters to our subscribers in the very kindliest spirit, primarily with the purpose of securing the information asked for our own guidance, and with no thought of deceiving or misleading anyone. So far as I can perceive, no man has been injured, but rather the cause of fair dealing between man and man, and the advertisers and the public, has been enhanced thereby. The one mistake I may have made was in failing to make the language of my letters sufficiently "judicial"—or indifferent—in tone.

Your suggestion that we "wish some excuse for participating in the benefits of his (Post) million-dollar advertising campaign" needs no comment. We have carried their business for years and see no reason why we should not continue to do so. Under the circumstances, it hardly seems necessary to state that the question of profit to us was not a factor in this straw vote—not in any sense of the word.

W. C. ABBOTT, Chicago.

COMMENT.—We publish the above "explanation" for what it is worth. The point of our criticism—dismissed by Dr. Abbott in three lines—was that a medical journal, in seeking to learn the attitude of its readers toward certain advertised products, should submit to its subscribers a series of leading questions so worded as, practically, to preclude any but favorable replies. It is not surprising that the answers to these letters sent out by the *American Journal of Clinical Medicine* were favorable to the products; the surprising thing is that there were any letters that were otherwise! The fact that there were nearly as many indifferent and condemnatory replies as there were replies praising the product, would, in view of the wording of the letter, have given pause to anyone who had not prejudged the question. The wish was evidently father to the thought. The letter said, in effect:

> We have been advertising Post's products for over ten years.
> We have always believed they were pure; we have used them and recommended them extensively.
> Will you cooperate by giving us your opinion?

Is it any wonder that the majority of the replies were favorable? Would there have been any "cooperation" in an unfavorable reply? Can anyone believe that evidence collected by such means has the slightest value? Of course, as testimonials, these answers doubtless have a distinct commercial value and there is little question that Mr. Post will find a use for those physicians' letters that have been so generously collected and forwarded him. In the famous suit in which Post was condemned to pay *Collier's* $50,000 for libel, Post was able to produce one favorable opinion of his products from a medical man—just one. Now he will have an abundance. As *Collier's* said, commenting on this, "It seems to us that, on every principle of give and take, the advertising of Postum and Grape-Nuts ought to continue to appear in the *American Journal of Clinical Medicine* for the next thousand years."

Treatment of Rhus Poisoning

To the Editor:—For many years I have known of a certain cure for poisoning from ivy and various species of rhus. This cure could be described briefly as the last thing that was put on. It was very much like the cures for vomiting of pregnancy. The last thing employed in any given case was a specific.

For something over forty years I have suffered from ivy poisoning, on an average, more than once a year. As a fisherman, hunter and horticulturist, no degree of caution sufficed to allow of my escape from ivy poisoning for an entire season when in America.

QUERIES AND MINOR NOTES

Not long ago I read of the discovery by Dr. Berryhill, of the United States Navy, that ivy poisoning was caused by an irritating oil produced in various parts of the plants of poisonous species of rhus, and that proper treatment consisted in scrubbing affected parts vigorously with hot soapsuds, followed by alcohol. A few days later while at a farm house I was poisoned on the hands and arms. Alcohol was applied freely, but the scrubbing brush and hot soapsuds were not available. It is often the case that one finds only the necessities like alcohol at a farm house, without any luxuries in the way of scrubbing brushes. The treatment with alcohol alone was not very effective, and my confidence went back to palliatives like hyposulphite of soda and acetate of lead. A week ago, I was again poisoned severely on the hands and arms. This time a good scrubbing was given with hot soapsuds and a brush, followed by scrubbing with ether on a rag. In five minutes it was evident that a cure had been effected. There was no discomfort at any subsequent moment. The red elevation at the sites of vesication lessened day by day, and without any irritation in evidence. Dr. Berryhill said nothing about the employment of ether, and it is probable that alcohol, as he suggested, would be better as a rule.

The gratification of finding this almost instantaneous cure for ivy poisoning is such that I publish the note as personal experience promptly.

Robert T. Morris, New York.

To the Editor:—There was what might be called an epidemic of skin diseases due to poison ivy at Woods Hole, Mass., this summer. Many of the students, investigators and employees at the U. S. Bureau of Fisheries laboratory suffered from it as did also many visitors. At the seashore an insect bite is usually the portal of entry of the rhus toxin. Not only mosquitoes but the so-called sand fleas are dangerous insects, if their bites precede or follow the poison ivy eruption. The manner of acquiring the eruption cannot always be explained. I know of one man who acquired it from his long-haired St. Bernard dog, who, after rolling in these plants on the way to the beach, would brush past his master's legs and thus infect him. Ladies often get it in drawing off their skirts and shoes that have come in contact with the plant.

There was no end of methods of treatment and as a rule when there are many kinds of treatments for one abnormality not one of them is effective. Therefore it is with much hesitancy that I add another method to this already swollen polypharmacy. But here the other methods had been tried and failed and my new plan was so universally beneficial that I cannot resist publishing it. There are two etiologic ideas that guided me. In the first place it was known that the active poison was an essential oil and therefore only solvents for oils which had a greater affinity for it than the cutaneous cells could remove it. In the second place it soon became evident to me from repeated microscopic examinations of the discharge that all severe cases, at least, are mixed skin infections, due to an invasion of bacteria—even pyogenic cocci—after the rhus had entered.

The first indication was met by an alkaline hot bath (ammonia or bicarbonate of sodium) added to a hot bath and liberal rubbing with ethereal antiseptic soap. Thereafter the parts are bathed in 85 per cent. alcohol and dried.

The second cause is met by the yellow oxid of mercury ointment most effectively.

℞

Unguenti hydrargyri oxidi flavi.................... ℥ss
Morphini .... gr. ij
M. Ointment.

There is however a third factor, the distress of the itching and the discharge. For this, after going through the above treatment in the morning, the following ointment should be applied at night.

℞

Bismuth subgallate .... 100 m
Solution epinephrin (adrenalin chlorid)—1:1000— ʒv
Lanolin .... ℥i
White petrolatum q. s. ....ad. ℥i

M. Sig: Ointment. Rub in liberally, then dust with an antiseptic powder.

But the yellow oxid of mercury ointment must precede this and the patient must avoid the locality where the rhus grows. The ethereal soap cannot be used around the eyes. Out of fourteen patients, ten were cured in eight days and the method soon acquired the reputation of a specific. Seven cases were so severe that the sufferers were confined to bed from four to eight days. The alkaline bath should be taken daily.

John C. Hemmeter, M.D., Ph.D., Baltimore.

Queries and Minor Notes

Anonymous Communications will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

FISH-POISONING

To the Editor:—Please give the bacteriology, pathology, diagnosis and treatment of so-called fish-poisoning or salmon-poisoning occurring among handlers of fish on the Pacific Coast.

L. B. Sims, M.D., Blaine, Wash.

Answer.—We presume that our correspondent refers to an obscure disease observed in employees connected with the salmon-canning business, especially among the Chinese laborers in the Alaska canneries and on the ships bound homeward after the close of the fishing season. Deaths during the voyage and after arrival at port are common, and serious illness affects a comparatively large number each year. On one vessel three weeks en route from Alaska to San Francisco, there were five deaths during the voyage, two more deaths in quarantine and twenty other cases of serious illness in a gang of about 125 coolies. The cases present such a noteworthy similarity of symptoms as to suggest a common cause. The disease begins with general weakness which gradually increases. In a few days the feet and legs become edematous and swollen, and the standing posture is difficult or impossible. There may be precordial discomfort, but there is no pain, no tenderness of nerves or muscles, no abnormality of reflexes and no fever. Respiration is accelerated, the heart action is weak and rapid, there is a systolic murmur, and the area of precordial dulness is increased. The only significant pathologic changes found post mortem are in the heart. This organ is enlarged, flabby and fatty; the muscle is pale, soft and easily torn; and the walls are very much thinner than normal. Bacteriologic examination is without positive results.

The clinical history and the post-mortem findings point to an acute degeneration of the heart-muscle, due to malnutrition. The primary cause of the disease seems to be found in the exhausting labor, poor quality of food and unhygienic surroundings. The sanitary conditions under which these laborers live, especially on shipboard, are described as frightful, and a public health officer (Lumsden, L. L.: Public Health Reports, U. S. P. H. and M.-H. S., xv, 1900) has said that "it is a crime against humanity that these helpless, irresponsible creatures should be herded together in this way, and allowed to remain amid all this filth during a voyage of about three weeks."

VASECTOMY

To the Editor:—Please give me references to literature on vasectomy—history, methods and results.

G. F.

Answer.—The physiologic effect of bilateral excision of a portion of the vas deferens, commonly called vasectomy, was studied on animals a century ago by Sir Astley Cooper, and has been investigated by many others since. The unanimous report is that no effect whatever can be detected, except the imprisonment of spermatozoa and consequent sterility. Both functions of the testicle—the so-called internal secretion necessary to adult masculinity, and the production of spermatozoa—continue unimpaired indefinitely. In a human subject, normal active spermatozoa were found in the testis seventeen years after the occlusion of the vas. Sexual desire and power continue unaffected, as they do also after bilateral occlusion of the vasa by gonococcus epididymitis, and in cases of congenital absence of the vasa.

In the human subject, excision of the diseased vas has long been a standard measure; bilateral excision of a piece of the normal duct was introduced by Lennander, in 1894, as a substitute for castration as a means of relieving the ills consecutive to prostatic hypertrophy; and for several years thereafter it had considerable vogue. This operation is used also to pre-

QUERIES AND MINOR NOTES

vent the recurrence of epididymitis resulting from chronic infection of prostate and vesicles; and it is often added to a prostatectomy to prevent epididymitis which is apt to follow the latter operation. Its employment for the purpose of erilizing mentally defective males, now authorized by law at least four states in the Union (Indiana, California, onnecticut and Iowa), began in Indiana in 1897; the measure as also been under consideration in a number of other states.

The operation is surgically and physiologically harmless; with local anesthesia a half-inch cut is made to the vas, the latter pulled up above the skin, about an inch of the duct excised, the cut ends ligated and dropped into the wound. Surgical cleanliness is requisite.

PHYSICIANS AND COCAIN PRESCRIBING

To the Editor:—Have I a right to use cocain in my prescription work and to give out the mixture myself in my own prescriptions? Have I also a right to prescribe or to send these cocain mixtures outside of the county or the state? Must the presence and percentage of cocain be stated?

F. F. E., Illinois.

ANSWER.—The federal government in "Food Inspection Decision 57" has declared the status of packages compounded according to physicians' prescriptions and entering into interstate commerce, as follows:

> "If a package compounded according to a physician's prescription be shipped, sent or transported from any state or territory or the District of Columbia to another state or territory or the District of Columbia by a compounder, druggist, physician, or their agents, by mail, express, freight, or otherwise, the label of such package is required to bear the information called for by Congress. If, however, the patient himself, or a member of his household, or the physician himself carries such package across a state line, and such package is not subject to sale, it is held that such package need not be marked so as to conform with the law, because such a transaction is not considered one of interstate commerce.
>
> "The package may be marked so as to comply with the act by either stamp, pen and ink or typewriter, provided all such written matter is distinctly legible and on the principal label, as prescribed in Regulation 17."

The national government has no jurisdiction over packages of medicine that do not go out of the state in which they are put up. The state in which our correspondent lives (Illinois) deals with the subject of cocain prescribing through its pharmacy law. Sections 14a and 14b of this law read as follows:

> "§ *14 a.* It shall be unlawful for any druggist or other person to retail, sell or give away any cocain, alpha or beta eucain, or any salt or any compound or derivative of any of the foregoing substances, or any preparation or compound containing any of the foregoing substances or any of their salts or compounds or derivatives, except on the written prescription of a duly registered physician, which prescription shall contain the name and address of the person for whom prescribed, and the date the same shall have been filled, and shall be permanently retained on file by the person, firm or corporation where the same shall have been filled, and it shall be filled but once, and of it no copy shall be taken by any person, and the original shall at all times be open to the inspection of the prescriber, to the State Board of Pharmacy, and all officers of the law; except, however, that such cocain, alpha or beta eucain, or any salt or any compound, or any derivative of the foregoing substances, or any preparation or compound containing any of the foregoing substances or any of their salts or compounds or derivatives, may lawfully be sold at wholesale on the written order of a licensed pharmacist, or licensed druggist, duly registered practicing physician, licensed veterinarian or licensed dentist, provided that the wholesale dealer shall affix or cause to be affixed to the bottle, box, vessel or package containing the article sold, and on the outside wrapper of the package as originally put up, a label, distinctly displaying the name and quantity of cocain, alpha or beta eucain, or any salt or compound or derivative of any of the foregoing substances sold, and the word "poison," with the name and place of business of the seller, all printed in red ink; and, provided also, that the wholesale dealer shall, before delivering any of the articles, make or cause to be made, in a book kept for the purpose, an entry of the sale thereof, stating the date of sale, the quantity, name and form in which sold, the name and address of the purchaser, and the name of the person by whom the entry is made; and the said book shall always be open for inspection by the proper authorities of the law, and shall be preserved for at least five years after the date of the last entry made therein.
>
> "§ *14 b.* It shall be unlawful for any duly registered physician, or other person, to prescribe, sell or offer for sale, dispense or give away any cocain, alpha or beta eucain, or any salt or compound or derivative of the foregoing substances, or any of their salts or compounds or derivatives, or preparation or compound containing any of the foregoing substances, to any person addicted to the habitual use of cocain, alpha or beta eucain, or any salt or compound or derivative of the foregoing substances, in any form."

BITES OF SNAKES, SPIDERS AND OTHER NOXIOUS CREATURES

To the Editor:—Please give references on symptoms and treatment of bite by (1) rattlesnake, (2) scorpion, (3) tarantula and (4) small black spider.

A. L. W.

ANSWER:—1. A full account of venomous serpents, including the rattlesnake, is found in the "Manual of Tropical Medicine," by Castellani and Chalmers (published by W. Wood & Co., 51 Fifth Avenue, New York. Ed. 1, price $6.00). The following references to the subject are found in the literature since 1905:

Rogers, L.: Snake-Bite Treated by Incision and Application of Permanganate of Potash, *Indian Med. Gaz.*, October, 1905; abstr. in THE JOURNAL, Dec. 9, 1905, p. 1830.

Ferguson, A. D.: Adrenalin Chlorid in the Treatment of Rattlesnake-Bite, *Tex Med. News*, November, 1906.

Haw, W. H.: Two Cases of Snake-Bite with Suggestions for Treatment, *Lancet*, April 27, 1907; abstr. in THE JOURNAL, May 25, 1907, p. 1819.

Baier, F. C.: Rattlesnake-Bite, with Recovery, *Northwest. Lancet*, June 15, 1907.

Braddock, C. S.: Treatment of Snake-Bites as Seen in the Jungle, *New York Med. Jour.*, Nov. 8, 1907; abstr. in THE JOURNAL, Nov. 23, 1907, p. 1803.

Willson, P.: Snake-Poisoning in the United States, *Arch. Int. Med.*, June, 1908; discussed editorially in THE JOURNAL, July 11, 1908, p. 132.

White, C. S.: Case of Poisoning from the Bite of a Rattlesnake, THE JOURNAL, May 8, 1909, p. 1486.

Lyon, W. C.: Venomous Snakes of the United States, *Mil. Surg.*, Wash, October, 1910.

In this connection a paragraph in the Vienna Letter in this issue will be of interest.

2. An extensive and excellent article is by H. V. Jackson: Poisonous Scorpion, Including a Review of Some Recent Literature and Personal Experiences, *Interstate Med. Jour.*, July, 1910. See also an article by C. Todd: Antiserum for Scorpion Venom, *Jour. Hyg.*, April, 1909; abstr. in THE JOURNAL, July 3, 1909, p. 82.

3. We find no articles on tarantula-poisoning. The tarantula produces merely local swelling and is not dangerous.

4. We cannot say from our correspondent's description which variety of spider is referred to. Castellani and Chalmers ("Manual of Tropical Medicine") describe the symptoms produced by the bite of several spiders, including *Lactrodectus mactans*, which is black with red spots. A case of a bite by this spider is reported, together with editorial comment on the spiders in general: Hodgdon, A. L.: Bite of a Poisonous Spider, *Lactrodectus mactans*, THE JOURNAL, May 4, 1907, p. 1507.

CASE FOR DIAGNOSIS

To the Editor:—I have a patient who began to suffer ten months ago with tingling in the ends of fingers and toes, which gradually traveled toward the trunk. Hypersensitiveness followed tenderness on pressure over the trunks of nerves. It has now reached the trunk, and, in fact, the whole extent of the peripheral nerves. The extra sensitiveness changes from one part of the body to the other with powerful pain in the cardiac regions, and the patient almost dies from pain in the heart, owing to contractions of muscles. In the precordial region there is a separation of costal cartilage from the ribs on the left side. Patient's appetite is now very good, bowels a little constipated, urine normal in quantity and quality, habits good. He has been in bed now about six months. Please give diagnosis and treatment. I call it "multiple peripheral neuritis."

DR. S. M. HENRY, Groom, Texas.

ANSWER.—The case as described is not like multiple peripheral neuritis, but suggests the onset of locomotor ataxia with severe girdle-pains or crises. Neuritis produces paralysis and anesthetic zones which are not described. It is desirable to know the condition of the patient's reflexes, whether there are anesthetic zones, whether there is any paralysis or ataxia or muscular atrophy and also his history as to exposure to alcoholic, lead or other poisoning or any of the infectious diseases which produce neuritis or locomotor ataxia and allied diseases. Is there disease of the costal cartilage or rib which are said to be separated: i. e., evidence of inflammation or trophic disease? The case is one for careful scientific investigation, as otherwise a correct diagnosis would be only possible by a fortunate guess. The diagnosis being made, the method of treatment will become clearer.

Not long ago I read of the discovery by Dr. Berryhill, of the United States Navy, that ivy poisoning was caused by an irritating oil produced in various parts of the plants of poisonous species of rhus, and that proper treatment consisted in scrubbing affected parts vigorously with hot soapsuds, followed by alcohol. A few days later while at a farm house I was poisoned on the hands and arms. Alcohol was applied freely, but the scrubbing brush and hot soapsuds were not available. It is often the case that one finds only the necessities like alcohol at a farm house, without any luxuries in the way of scrubbing brushes. The treatment with alcohol alone was not very effective, and my confidence went back to palliatives like hyposulphite of soda and acetate of lead. A week ago, I was again poisoned severely on the hands and arms. This time a good scrubbing was given with hot soapsuds and a brush, followed by scrubbing with ether on a rag. In five minutes it was evident that a cure had been effected. There was no discomfort at any subsequent moment. The red elevation at the sites of vesication lessened day by day, and without any irritation in evidence. Dr. Berryhill said nothing about the employment of ether, and it is probable that alcohol, as he suggested, would be better as a rule.

The gratification of finding this almost instantaneous cure for ivy poisoning is such that I publish the note as personal experience promptly.

Robert T. Morris, New York.

To the Editor:—There was what might be called an epidemic of skin diseases due to poison ivy at Woods Hole, Mass., this summer. Many of the students, investigators and employees at the U. S. Bureau of Fisheries laboratory suffered from it as did also many visitors. At the seashore an insect bite is usually the portal of entry of the rhus toxin. Not only mosquitoes but the so-called sand fleas are dangerous insects, if their bites precede or follow the poison ivy eruption. The manner of acquiring the eruption cannot always be explained. I know of one man who acquired it from his long-haired St. Bernard dog, who, after rolling in these plants on the way to the beach, would brush past his master's legs and thus infect him. Ladies often get it in drawing off their skirts and shoes that have come in contact with the plant.

There was no end of methods of treatment and as a rule when there are many kinds of treatments for one abnormality not one of them is effective. Therefore it is with much hesitancy that I add another method to this already swollen polypharmacy. But here the other methods had been tried and failed and my new plan was so universally beneficial that I cannot resist publishing it. There are two etiologic ideas that guided me. In the first place it was known that the active poison was an essential oil and therefore only solvents for oils which had a greater affinity for it than the cutaneous cells could remove it. In the second place it soon became evident to me from repeated microscopic examinations of the discharge that all severe cases, at least, are mixed skin infections, due to an invasion of bacteria—even pyogenic cocci—after the rhus had entered.

The first indication was met by an alkaline hot bath (ammonia or bicarbonate of sodium) added to a hot bath and liberal rubbing with ethereal antiseptic soap. Thereafter the parts are bathed in 85 per cent. alcohol and dried.

The second cause is met by the yellow oxid of mercury ointment most effectively.

℞

Unguenti hydrargyri oxidi flavi....................	℥ss
Morphini	gr. ij

M. Ointment.

There is however a third factor, the distress of the itching and the discharge. For this, after going through the above treatment in the morning, the following ointment should be applied at night.

℞

Bismuth subgallate	100 ♏
Solution epinephrin (adrenalin chlorid)—1 :1000—	ʒv
Lanolin	℥i
White petrolatum q. s.......................ad.	℥i

M. Sig: Ointment. Rub in liberally, then dust with an antiseptic powder.

But the yellow oxid of mercury ointment must precede this and the patient must avoid the locality where the rhus grows. The ethereal soap cannot be used around the eyes. Out of fourteen patients, ten were cured in eight days and the method soon acquired the reputation of a specific. Seven cases were so severe that the sufferers were confined to bed from four to eight days. The alkaline bath should be taken daily.

John C. Hemmeter, M.D., Ph.D., Baltimore.

Queries and Minor Notes

Anonymous Communications will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

FISH-POISONING

To the Editor:—Please give the bacteriology, pathology, diagnosis and treatment of so-called fish-poisoning or salmon-poisoning occurring among handlers of fish on the Pacific Coast.

L. B. Sims, M.D., Blaine, Wash.

Answer.—We presume that our correspondent refers to an obscure disease observed in employees connected with the salmon-canning business, especially among the Chinese laborers in the Alaska canneries and on the ships bound homeward after the close of the fishing season. Deaths during the voyage and after arrival at port are common, and serious illness affects a comparatively large number each year. On one vessel three weeks en route from Alaska to San Francisco, there were five deaths during the voyage, two more deaths in quarantine and twenty other cases of serious illness in a gang of about 125 coolies. The cases present such a noteworthy similarity of symptoms as to suggest a common cause. The disease begins with general weakness which gradually increases. In a few days the feet and legs become edematous and swollen, and the standing posture is difficult or impossible. There may be precordial discomfort, but there is no pain, no tenderness of nerves or muscles, no abnormality of reflexes and no fever. Respiration is accelerated, the heart action is weak and rapid, there is a systolic murmur, and the area of precordial dulness is increased. The only significant pathologic changes found post mortem are in the heart. This organ is enlarged, flabby and fatty; the muscle is pale, soft and easily torn; and the walls are very much thinner than normal. Bacteriologic examination is without positive results.

The clinical history and the post-mortem findings point to an acute degeneration of the heart-muscle, due to malnutrition. The primary cause of the disease seems to be found in the exhausting labor, poor quality of food and unhygienic surroundings. The sanitary conditions under which these laborers live, especially on shipboard, are described as frightful, and a public health officer (Lumsden, L. L.: Public Health Reports, U. S. P. H. and M.-H. S., xv, 1900) has said that "it is a crime against humanity that these helpless, irresponsible creatures should be herded together in this way, and allowed to remain amid all this filth during a voyage of about three weeks."

VASECTOMY

To the Editor:—Please give me references to literature on vasectomy—history, methods and results.

G. F.

Answer.—The physiologic effect of bilateral excision of a portion of the vas deferens, commonly called vasectomy, was studied on animals a century ago by Sir Astley Cooper, and has been investigated by many others since. The unanimous report is that no effect whatever can be detected, except the imprisonment of spermatozoa and consequent sterility. Both functions of the testicle—the so-called internal secretion necessary to adult masculinity, and the production of spermatozoa—continue unimpaired indefinitely. In a human subject, normal active spermatozoa were found in the testis seventeen years after the occlusion of the vas. Sexual desire and power continue unaffected, as they do also after bilateral occlusion of the vasa by gonococcus epididymitis, and in cases of congenital absence of the vasa.

In the human subject, excision of the diseased vas has long been a standard measure; bilateral excision of a piece of the normal duct was introduced by Lennander, in 1894, as a substitute for castration as a means of relieving the ills consecutive to prostatic hypertrophy; and for several years thereafter it had considerable vogue. This operation is used also to pre-

QUERIES AND MINOR NOTES

vent the recurrence of epididymitis resulting from chronic infection of prostate and vesicles; and it is often added to a prostatectomy to prevent epididymitis which is apt to follow the latter operation. Its employment for the purpose of sterilizing mentally defective males, now authorized by law in at least four states in the Union (Indiana, California, Connecticut and Iowa), began in Indiana in 1897; the measure has also been under consideration in a number of other states.

The operation is surgically and physiologically harmless; with local anesthesia a half-inch cut is made to the vas, the latter pulled up above the skin, about an inch of the duct excised, the cut ends ligated and dropped into the wound. Surgical cleanliness is requisite.

PHYSICIANS AND COCAIN PRESCRIBING

To the Editor:—Have I a right to use cocain in my prescription work and to give out the mixture myself in my own prescriptions? Have I also a right to prescribe or to send these cocain mixtures outside of the county or the state? Must the presence and percentage of cocain be stated?

F. F. E., Illinois.

ANSWER.—The federal government in "Food Inspection Decision 57" has declared the status of packages compounded according to physicians' prescriptions and entering into interstate commerce, as follows:

> "If a package compounded according to a physician's prescription be shipped, sent or transported from any state or territory or the District of Columbia to another state or territory or the District of Columbia by a compounder, druggist, physician, or their agents, by mail, express, freight, or otherwise, the label or such package is required to bear the information called for by Congress. If, however, the patient himself, or a member of his household, or the physician himself carries such package across a state line, and such package is not subject to sale, it is held that such package need not be marked so as to conform with the law, because such a transaction is not considered one of interstate commerce.
>
> "The package may be marked so as to comply with the act by either stamp, pen and ink or typewriter, provided all such written matter is distinctly legible and on the principal label, as prescribed in Regulation 17."

The national government has no jurisdiction over packages of medicine that do not go out of the state in which they are put up. The state in which our correspondent lives (Illinois) deals with the subject of cocain prescribing through its pharmacy law. Sections 14a and 14b of this law read as follows:

> "§ *14 a.* It shall be unlawful for any druggist or other person to retail, sell or give away any cocain, alpha or beta eucain, or any salt or any compound or derivative of any of the foregoing substances, or any preparation or compound containing any of the foregoing substances or any of their salts or compounds or derivatives, except on the written prescription of a duly registered physician, which prescription shall contain the name and address of the person for whom prescribed, and the date the same shall have been filled, and shall be permanently retained on file by the person, firm or corporation where the same shall have been filled, and it shall be filled but once, and of it no copy shall be taken by any person, and the original shall at all times be open to the inspection of the prescriber, to the State Board of Pharmacy, and all officers of the law; except, however, that such cocain, alpha or beta eucain, or any salt or any compound, or any derivative of the foregoing substances, or any preparation or compound containing any of the foregoing substances or any of their salts or compounds or derivatives, may lawfully be sold at wholesale on the written order of a licensed pharmacist, or licensed druggist, duly registered practicing physician, licensed veterinarian or licensed dentist, provided that the wholesale dealer shall affix or cause to be affixed to the bottle, box, vessel or package containing the article sold, and on the outside wrapper of the package as originally put up, a label, distinctly displaying the name and quantity of cocain, alpha or beta eucain, or any salt or compound or derivative of any of the foregoing substances sold, and the word "poison," with the name and place of business of the seller, all printed in red ink; and, provided also, that the wholesale dealer shall, before delivering any of the articles, make or cause to be made, in a book kept for the purpose, an entry of the sale thereof, stating the date of sale, the quantity, name and form in which sold, the name and address of the purchaser, and the name of the person by whom the entry is made; and the said book shall always be open for inspection by the proper authorities of the law, and shall be preserved for at least five years after the date of the last entry made therein.
>
> "§ *14 b.* It shall be unlawful for any duly registered physician, or other person, to prescribe, sell or offer for sale, dispense or give away any cocain, alpha or beta eucain, or any salt or compound or derivative of the foregoing substances, or any of their salts or compounds or derivatives, or preparation or compound containing any of the foregoing substances, to any person addicted to the habitual use of cocain, alpha or beta eucain, or any salt or compound or derivative of the foregoing substances, in any form."

BITES OF SNAKES, SPIDERS AND OTHER NOXIOUS CREATURES

To the Editor:—Please give references on symptoms and treatment of bite by (1) rattlesnake, (2) scorpion, (3) tarantula and (4) small black spider.

A. L. W.

ANSWER:—1. A full account of venomous serpents, including the rattlesnake, is found in the "Manual of Tropical Medicine," by Castellani and Chalmers (published by W. Wood & Co., 51 Fifth Avenue, New York. Ed. 1, price $6.00). The following references to the subject are found in the literature since 1905:

Rogers, L.: Snake-Bite Treated by Incision and Application of Permanganate of Potash, *Indian Med. Gaz.*, October, 1905; abstr. in THE JOURNAL, Dec. 9, 1905, p. 1830.

Ferguson, A. D.: Adrenalin Chlorid in the Treatment of Rattlesnake-Bite, *Tex. Med. News*, November, 1906.

Haw, W. H.: Two Cases of Snake-Bite with Suggestions for Treatment, *Lancet*, April 27, 1907; abstr. in THE JOURNAL, May 25, 1907, p. 1819.

Baier, F. C.: Rattlesnake-Bite, with Recovery, *Northwest. Lancet*, June 15, 1907.

Braddock, C. S.: Treatment of Snake-Bites as Seen in the Jungle, *New York Med. Jour.*, Nov. 8, 1907; abstr. in THE JOURNAL, Nov. 23, 1907, p. 1803.

Willson, P.: Snake-Poisoning in the United States, *Arch. Int. Med.*, June, 1908; discussed editorially in THE JOURNAL, July 11, 1908, p. 132.

White, C. S.: Case of Poisoning from the Bite of a Rattlesnake, THE JOURNAL, May 8, 1909, p. 1486.

Lyon, W. C.: Venomous Snakes of the United States, *Mil. Surg.*, Wash, October, 1910.

In this connection a paragraph in the Vienna Letter in this issue will be of interest.

2. An extensive and excellent article is by H. V. Jackson: Poisonous Scorpion, Including a Review of Some Recent Literature and Personal Experiences, *Interstate Med. Jour.*, July, 1910. See also an article by C. Todd: Antiserum for Scorpion Venom, *Jour. Hyg.*, April, 1909; abstr. in THE JOURNAL, July 3, 1909, p. 82.

3. We find no articles on tarantula-poisoning. The tarantula produces merely local swelling and is not dangerous.

4. We cannot say from our correspondent's description which variety of spider is referred to. Castellani and Chalmers ("Manual of Tropical Medicine") describe the symptoms produced by the bite of several spiders, including *Lactrodectus mactans*, which is black with red spots. A case of a bite by this spider is reported, together with editorial comment on the spiders in general: Hodgdon, A. L.: Bite of a Poisonous Spider, *Lactrodectus mactans*, THE JOURNAL, May 4, 1907, p. 1507.

CASE FOR DIAGNOSIS

To the Editor:—I have a patient who began to suffer ten months ago with tingling in the ends of fingers and toes, which gradually traveled toward the trunk. Hypersensitiveness followed tenderness on pressure over the trunks of nerves. It has now reached the trunk, and, in fact, the whole extent of the peripheral nerves. The extra sensitiveness changes from one part of the body to the other with powerful pain in the cardiac regions, and the patient almost dies from pain in the heart, owing to contractions of muscles. In the precordial region there is a separation of costal cartilage from the ribs on the left side. Patient's appetite is now very good, bowels a little constipated, urine normal in quantity and quality, habits good. He has been in bed now about six months. Please give diagnosis and treatment. I call it "multiple peripheral neuritis."

DR. S. M. HENRY, Groom, Texas.

ANSWER.—The case as described is not like multiple peripheral neuritis, but suggests the onset of locomotor ataxia with severe girdle-pains or crises. Neuritis produces paralysis and anesthetic zones which are not described. It is desirable to know the condition of the patient's reflexes, whether there are anesthetic zones, whether there is any paralysis or ataxia or muscular atrophy and also his history as to exposure to alcoholic, lead or other poisoning or any of the infections which produce neuritis or locomotor ataxia and allied diseases. Is there disease of the costal cartilage or rib which are said to be separated: i. e., evidence of inflammation or trophic disease? The case is one for careful scientific investigation, as otherwise a correct diagnosis would be only possible by a fortunate guess. The diagnosis being made, the method of treatment will become clearer.

The Public Service

Medical Department, U. S. Army

Changes during the week ended Sept. 16, 1911.

Stone, Frank P., dental surgeon, reported for duty at Fort Barrancas, Fla.

Wing, Franklin F., dental surgeon, returned to Fort D. A. Russell, Wyo., from temporary duty at Fort Logan, Colo.

Boak, S. D., dental surgeon, left West Point, N. Y., on thirty days' leave of absence.

Thomason, Henry D., captain, ordered to Milwaukee, Wis., for the purpose of reading a paper before the Association of Military Surgeons of the United States, Sept. 26 to 29, 1911.

Richard, Charles, colonel, leave of absence extended ten days.

Ferenbaugh, Thomas L., and Gentry, Ernest R., lieuts., relieved from duty in the Department of Texas and will return to proper stations.

Bowen, Albert S., lieut., ordered to Fort Snelling, Minn., for temporary duty; granted thirty days' leave of absence.

Maus, L. Mervin, colonel, leave of absence extended ten days.

Suggs, Frank, M.R.C., granted eighteen days' leave of absence.

Whitney, Walter, M.R.C., ordered to proceed from Fort McPherson, Ga., to Fort Dale, Fla., for temporary duty at the latter post.

Eliot, Henry W., M.R.C., granted thirty days' leave of absence.

Tetrault, Charles A., M.R.C., ordered to proceed from Fort Michie, N. Y., to Fort H. G. Wright, N. Y., for temporary duty.

Changes during the week ended Sept. 23, 1911.

McAlister, John A., Jr., dental surgeon, ordered to proceed from Fort Sam Houston, Texas, to Camp Cloudroft, N. Mex., for temporary duty.

Millikin, John D., dental surgeon, arrived at San Francisco from Philippine Islands and left same date on two months' leave of absence.

Burket, John A., lieut., granted leave of absence from Oct. 3, 1911, to such date as it may be necessary for him to start for the Philippine Islands.

Norman, Seaton, M.R.C., on expiration of present leave will proceed to Fort Clark, Texas, for duty. Lieutenant Norman will stand relieved from duty at Fort Clark at such time as will enable him to comply with orders hereinafter given, and will proceed to his home and stand relieved from further active duty in the Medical Reserve Corps, March 1, 1912.

Russell, F. F., major, ordered to New York City and Boston to investigate recent bacteriological developments in connection with course of instruction at the Army Medical School in this city.

Smith, William H., lieut., granted ten days' leave of absence.

Thomason, Henry D., captain, is detailed to attend the annual meeting of the National Guard Association of the United States, Buffalo, N. Y., Oct. 9 to 11, 1911.

Winter, Francis A., major, ordered to proceed to St. Louis and Jefferson Barracks, Mo., on official business.

Marrow, Charles E., major, granted leave of absence for two months, about Sept. 10, 1911.

McAlister, John A., Jr., dental surgeon, left Fort Sam Houston, Texas, en route to Camp Cloudcroft, N. Mex., for temporary duty.

Little, William L., captain, ordered to proceed from Fort Adams, R. I., to Springfield Armory, Mass., for physical examination of officers stationed at that place, about Sept. 25, 1911.

Hughes, Leonard S., lieut., granted ten days' leave of absence about Nov. 20, 1911.

Rich, Edwin W., captain, will, in addition to his other duties, assume charge of the medical supply depot, San Francisco, during the absence of Colonel William W. Gray, Medical Corps.

Hungerford, George H., M.R.C., resignation accepted.

Buchsbaum, Maurice, M.R.C., ordered to Army General Hospital, San Francisco, for observation and treatment.

McIntyre, captain, granted leave of absence for three months when his services can be spared, with permission to go beyond sea.

Fletcher, John P., lieut., granted leave of absence for one month.

Tetrault, Charles A., M.R.C., assigned to permanent station at Fort H. G. Wright, N. Y.

Craig, Charles F., capt., is detailed to attend the meeting of the Southern Medical Association, at Hattiesburg, Miss., Nov. 14 to 16, 1911.

Robbins, Chandler P., major, granted fourteen days' leave.

Voorhies, Hugh G., dental surgeon, granted twenty days' leave.

Kirkpatrick, Thomas J., major, granted ten days' leave.

Bushnell, George E., colonel, granted thirty days' leave.

Davis, William T., captain, granted ten days' leave of absence.

U. S. Public Health and Marine-Hospital Service

Changes for the seven days ended Sept. 20, 1911.

Guiteras, G. M., surgeon, detailed to represent the service at the fifth international sanitary conference of American republics, to be held at Santiago, Chile, Nov. 5-12, 1911.

Ramus, Carl, P. A. surgeon, granted seven days' leave of absence from Aug. 24, 1911, under paragraph 189, Service Regulations.

Warren, B. S., P. A. surgeon, granted ten days' leave of absence from Sept. 20, 1911.

Stimson, A. M., P. A. surgeon, directed to proceed to Detroit, Chicago and Milwaukee on special temporary duty. Detailed to attend the meeting of the Michigan State Medical Society, in Detroit, Sept. 27 and 28, 1911, and the meeting of the Chicago Medical Society, Oct. 4, 1911.

Krulish, E., asst.-surg., granted one month's leave of absence from Sept. 12, 1911.

Bond, B. D., A. A. surgeon, granted leave of absence, without pay, for the period Aug. 25, 1911, to Jan. 1, 1912.

Crepin, H. E., A. A. surgeon, granted twenty-one days' leave of absence from Sept. 1, 1911.

Fairbanks, George D., A. A. surgeon, granted thirty days' leave of absence from Sept. 11, 1911.

Markoe, W. W., A. A. surgeon, granted thirty days' leave of absence from Sept. 19, 1911.

Marsh, W. H., A. A. surgeon, granted eleven days' leave of absence from Sept. 23, 1911.

Medical Economics

THE NATIONAL GRANGE AND A DEPARTMENT OF HEALTH

In his remarkable speech before the United States Senate, in July, Senator Works of California said that the National Grange had withdrawn its endorsement of a national department of health. In an open letter addressed to Senator Works, the secretary of the Conference of Progressive State Granges cites the official proceeding of the National Grange to show that, instead of repudiating its endorsement of a department of health, the National Grange reaffirmed its approval of the establishment of such a department. Mr. Hampton's letter is worthy of careful reading.[1]

"*Hon. John D. Works, United States Senate, Washington, D. C.*

"Dear Sir.- I have read with great care your speech opposing Senator Owen's bill to establish a department of health, as published in the *Christian Science Monitor* of July 11.

"You support your argument with quotations from various authorities, among them resolutions purporting to have been forwarded by C. M. Freeman, secretary of the National Grange, showing that the National Grange had completely reversed its position. If Mr. Freeman forwarded such resolutions in the form in which you have published them, he knowingly misrepresented the action of the National Grange, and his action will undoubtedly be investigated by that body at its next annual meeting.

"To prove to you that the Grange position endorsing the establishment of a federal bureau of public health was not reversed by the National Grange at Atlantic City, or by any state granges of large membership at their state meetings of later date, I submit:

"(*a*) Page 167 of the official proceedings of the Atlantic City session, containing the introduction of the general report of the Committee on Resolutions, the opening part of which reads as follows: 'We reaffirm the resolutions and declarations of the general report of the Committee on Resolutions, made and unanimously adopted at the forty-third annual session, held one year ago at Des Moines, Iowa, on public health bureau, on home economics, on tariff revision,' etc.

"(*b*) The April, 1911, issue of the *Michigan Patron* (the official organ of a number of state granges, aggregating a large percentage of the total grange membership) contains an editorial, 'The Grange Position on Public Health,' in which a statement made in a circular letter by the League for Medical Freedom, that the Grange had reversed its position on public health, is reviewed at length and proved not true. This proof, you will note, includes resolutions by the National Grange and editorials by the national master.

"(*c*) A copy of the health resolutions adopted by the Maine State Grange at its annual meeting in Augusta, Dec. 20-22, 1910. The points in these resolutions to which I especially desire to call your attention are: 'That we reindorse the establishment of a federal bureau of public health, as set forth in the resolutions adopted by the National Grange at the forty-third annual session at Des Moines, Iowa, Nov. 10-20, 1909, provided that such legislation properly safeguards the rights of all schools of medical practice,' and 'That the Conference of State Granges is urged to take such action as may be expedient to unite all farmers in supporting a public health policy in the interests of all the people, and that the conference appeals to all public-spirited citizens to unite with the farmers in this important work.'

"You will notice from the above (*a*) that the *first* of the public measures *re*-indorsed by the National Grange at Atlantic City was the action of the Des Moines meeting in 1909, on public health. I submit the resolution thus emphatically *re*-indorsed:

"'*Resolved*, That the National Grange favors the establishment of a national health bureau or commission, and urges on Congress the necessity for the immediate enactment of legislation for this purpose.'

"I sincerely believe you would not willingly help to place the Grange in a false light before the country, but I feel you have been misled, and have unwittingly been made the means by which this has been done. And as your speech has been given wide publicity in the *Congressional Record* and in the public press, I address this open letter to you in order that the true position of the Grange may be placed before Congress and the people.

---

[1] See also Current Comment, page 1140.

"For the honest opposition of yourself and the Christian Scientists in general, I have the most sincere respect; but it is the opposition which seeks to gain its object by tricks and misrepresentations, and by exciting the fears and prejudices of the people, which convinces us that back of all the honest opposition—and no doubt unknown to it—are the same interests that are fighting the pure food laws, and which, even at this writing, hope to succeed in forcing Dr. Wiley out of office.

"It is this opposition which we feel should be forced out into the open, where its nature can be fully understood. If this is done, it will at once remove much of the present misunderstanding, and Christian Scientists and all who sincerely desire honest medical freedom should assist in accomplishing this.

"Christian Scientists fear the consequences that would follow the enactment of such legislation as the Owen bill proposes. If that fear is well founded, and your belief that the American Medical Association is a medical trust is well founded, is it not time that the country knew these and all the facts relating to this burning question? What possible better means have we than a rigid Congressional investigation by a committee specially organized for that purpose?

"The House of Representatives, as at present constituted, is believed to be honestly desirous of serving the people. It is investigating the trusts, probing into the expenditures of the various departments of the government, and why should it not have a committee on health and thoroughly investigate this matter of such vital importance to all the people. Surely the Christian Scientists are not opposed to honest investigation by a committee having power to probe every charge and countercharge to the bottom.

"The farmers want the facts and a square deal for all the people—Christian Scientists and all schools of medicine included—and Christian Scientists should join with them in their present efforts to get Congress to appoint a committee on public health and promptly institute a thorough investigation Farmers and Christian Scientists should not work at cross-purposes on so important a matter. Honest investigation by Congress is the way to bring them together, and I appeal to you to use all your influence to bring this about

"George P. Hampton.
"Secretary, Conference Progressive State Granges."

POSTGRADUATE COURSE FOR COUNTY SOCIETIES

[Note.—The pamphlets containing the outline of the postgraduate study course for county societies for the coming year are ready for distribution. Secretaries of county societies can secure supplies by writing to the Secretary, Council on Health and Public Instruction, American Medical Association, 535 Dearborn Ave., Chicago.]

First Month—Fourth Weekly Meeting

Papilloma: Origin, Structure, Varieties

Warts: Microscopic section, distribution, number, pigment, secondary changes.

Villous Papilloma: Structure, gross and microscopic, prognosis.

Intracystic Papilloma: Structure, gross and microscopic, distribution.

Psammoma: Structure, chemistry, location, prognosis.

Adenoma

Structure, varieties, capsule, fluid, recurrence, infiltration; secondary changes.

Dermoids: Structure, Distribution

Sequestration Dermoids: Location, mode of origin, contents, prognosis.

Tubulo-Dermoids: Distribution, contents, size.

Lingual, Branchial and Rectal: Location of each.

Ovarian Dermoids: Origin, structure, contents, size, age.

Moles: Distribution, structure, secondary changes.

Teratoma

Differentiate from dermoids.

Cysts: Mode of Origin, Structure, Contents

Retention cysts, tubulo-cysts, hydroceles and gland cysts.

Monthly Meeting

The Differential Diagnosis of Benign and Malignant Tumors.

The Problem of Metastasis in the Treatment of Malignant Tumors.

The Diagnosis and Treatment of Tumors of Long Bones.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

Arizona: Phoenix, October 2-3. Sec., Dr. Ancil Martin.

Colorado: The State Capitol, Denver, October 3. Sec., Dr. David A. Strickler, 612 Empire Building.

Georgia: Regular, Atlanta, October 10. Sec., Dr. C. T. Nolan, Marietta. Homeopathic, Atlanta, October 10. Sec., Dr. R. E. Hinman, 106½ Whitehall Street.

Idaho: Wallace, October 3-4. Sec., Dr. O. J. Allen, Bellevue.

Illinois: Coliseum Annex, Chicago, October 26-28. Sec., Dr. J. A. Egan, Springfield.

Kansas: National Hotel, Topeka, October 10-12. Sec., Dr. H. A. Dykes, Lebanon.

Louisiana: New Orleans, October 19-21. Sec., Dr. A. B. Brown, 108 Baronne Street.

Michigan: Legislative Bldg., Lansing, October 10-12. Sec., Dr. B. D. Harison, 504 Washington Arcade, Detroit.

Minnesota: State University Minneapolis, October 3. Sec., Dr. W. S. Fullerton, St. Paul.

Mississippi: State Capitol, Jackson, October 10-11. Sec., Dr. S. H. McLean.

Montana: The Capitol, Helena, October 3. Sec., Dr. W. C. Riddell.

New Jersey: The State Capitol, Trenton, October 17-18. Sec., Dr. H. G. Norton, 429 E. State Street.

New Mexico: The Capitol, Santa Fe, October 9-10. Sec., Dr. J. A. Massie.

Oklahoma: Muskogee, October 10. Sec., Dr John W. Duke, Guthrie

Rhode Island: Room 315 State House, Providence, October 5-6. Sec., Dr. Gardner T. Swarts.

Utah: Salt Lake City, October 2-3. Sec., Dr. G. F. Harding, 310 Templeton Building.

Wyoming: Riverton, October 9-11. Sec., Dr. A. B. Tonkin.

Illinois January Report

Dr. James A. Egan, secretary of the Illinois State Board of Health, reports the written examination held at Chicago, January 11-13, 1911. The number of subjects examined in was 16, total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 53, of whom 17 passed and 32 failed. Three candidates did not complete the examination and one withdrew. The following colleges were represented:

College	Year Grad.	Total No. Examined
PASSED		
University of Arkansas	(1909)	1
American Medical Missionary College	(1903)	1
Chicago College of Medicine and Surgery	(1910)	1
Northwestern University Medical School	(1889) (1910)	2
National Medical University	(1909)	1
College of Physicians and Surgs., Chicago	(1904) (1910)	2
Reliance Medical College	(1910)	1
Rush Medical College	(3, 1910) (1911)	4
St. Louis College of Physicians and Surgeons	(1910)	1
Jefferson Medical College	(1908)	1
University of Pennsylvania	(1886) (1908)	2
FAILED		
Bennett Medical College	(1909) (5, 1910) (1911)	7
Hahnemann Medical College and Hospital, Chicago	(1909)	1
Hering Medical College	(1910)	2
Jenner Medical College	(1910)	2
College of Medicine and Surgery, Physio-Medical	(1910)	3
National Medical University	(1909)	1
College of Phys. and Surgs.	(1907) (1908) (2, 1910)	4
Keokuk Medical College, Coll. of Phys. and Surgs.	(1908)	1
Hospital Medical College, Louisville	(1904)	1
Louisville and Hospital Medical College	(1908)	1
Barnes Medical College	(1907) (2, 1910)	3
St. Louis University	(1907)	1
Miami Medical College	(1909)	1
Meharry Medical College	(1902) (1909) (1910)	3
Western University, London, Ontario	(1892)	1

Tennessee May Report

Dr. C. A. Abernathy, secretary of the Tennessee State Board of Medical Examiners, reports the written and oral examinations held at Nashville, Knoxville and Memphis, May 2-3, 1911. The total number of subjects examined in was 8; total number of questions asked, 64; percentage required to pass, 75. The total number of candidates examined was 276, of whom 213 passed, including 110 non-graduates, and 42 failed, including 30 non-graduates. Twenty-one candidates received temporary licenses, including 9 non-graduates. The following colleges were represented:

The grade for one non-graduate was not obtained.

* These two applicants made the requisite grade to pass, but charges of fraud have been brought, and they most probably will be rejected; hence they are put in the list of those who failed.

The following questions were asked:

ANATOMY

1. Describe the portal system. Name the ductless glands. 3. What cranial nerve has the widest distribution? 4. Give the origin and insertion of the humeral biceps muscle. 5. Mention any one muscle that moves the humerus forward, backward or inward. 6. Describe Hunter's canal. (a) What passes through it? 7. Describe the periosteum. 8. What muscles for the tendo Achillis?

PHYSIOLOGY

1. Give composition and properties of chyle. 2. Give composition of the blood. 3. Describe secretion, properties and composition of gastric juice. 4. Give the physiologic anatomy of the testicles. 5. Describe the physiologic anatomy of the tongue concerned in gestation. 6. Give the physiologic anatomy of the mammary glands. 7. Describe the excretion of urine. 8. Name all the enzymes required to digest bread.

PATHOLOGY

1. What is stomatitis? Give the pathology of ulcerative stomatitis. 2. Describe any one pathologic condition caused by the excessive use of alcohol. 3. Describe the pathologic changes which take place in the lung in lobar pneumonia. 4. Give the pathology of parenchymatous goiter. 5. Describe the pathology of the inflammation of any one serous membrane. 6. Describe the pathology of chronic lead poison. 7. Describe the pathology of cerebrospinal meningitis. 8. Describe the pathologic condition caused by the bite of a mosquito.

MATERIA MEDICA

1. Write a prescription for chronic malaria and state how long the patient should take it. 2. Name two medicines which increase the flow of urine. The source and dose of each. 3. What is the source of digitalis and hyoscyamus? What preparation would you use and the dose of each? 4. What is the source of potassium iodid and what is the dose? Name three diseases for which you would give it. 5. Give the source of iodid of lime and iodid of soda and the dose of each. 6. What is sodium sulphate? 7. What is the source of tetanus antitoxin? 8. What is the source of cascara sagrada? What preparation would you use and what would be the dose?

CHEMISTRY

1. Describe Esbach's albuminometer and give a quantitative test for albumin. 2. Give a chemical test for pus in the urine; (a)-for blood. 3. What is urea? (a) Its estimation? (b) Of what significance in nephritis? 4. What are alcohols and how classified? 5. Give chemical formula for iodoform. (a) How prepared. (b) Physiologic effects. 6. What is a simple ether? (a) Compound ether? (b) Formula for sulphuric ether? 7. What is benzine? (a) Chemical formula and properties? 8. What is arsenic? (a) Occurrence? (b) Preparation? (c) Properties? (d) Reinsch's test for arsenic?

OBSTETRICS

1. Describe, anatomically, the internal generative organs of the female. (a) State the function of each. 2. What are the dangers of traction on the child and on the placenta? 3. What is involution? (a) How long a time is usually required for this process? (b) What causes may operate to delay or prevent it? 4. Describe the immediate care of the new-born child when from any cause the mother cannot nurse it. (a) Give rules for artificial feeding. 5. Differentiate eutocia and dystocia. Mention important varieties of the latter and give their management. 6. In a labor otherwise normal but tedious, how soon would it be proper to interfere, and what symptoms would prompt such a course? 7. When does it become proper to perform craniotomy, and how should that operation be performed? 8. Define puerperal phlebitis and give its pathology, symptoms and treatment.

SURGERY

1. How would you diagnose a case of complete inguinal hernia from a hydrocele, and describe the radical cure for hydrocele? 2. Describe in full Bassini's method of operation for the radical cure of hernia. 3. Give the nature and treatment of Pott's fracture. 4. Where does senile gangrene most often occur, and what is the usual cause? 5. Give symptoms and treatment of cholelithiasis. 6. Define peritonitis. State three ways in which the peritoneum may be invaded by bacteria. 7. What are the causes and treatment of paraphimosis? 8. Differentiate dislocation of the head of the femur from fracture of the neck, and give main essentials of treatment of each.

PRACTICE QUESTIONS

1. Name the organic diseases of the heart. Define aortic stenosis. Give the physical signs of it. 2. Define lobar pneumonia. Give general symptoms of diagnosis. Give briefly a treatment. 3. What is the pulse? Name some of the varieties of the pulse and their significance. 4. Define acute Bright's disease. What are the most frequent etiologic factors which produce this form of kidney disease? Give a treatment. 5. Define leukocytosis. Define leukopenia. Name four diseases in which the leukocytes are increased in number. Name four diseases in which the leukocytes are normal or diminished. 6. Define diabetes mellitus. Differentiate between diabetes mellitus and diabetes insipidus. Give a diet for diabetes mellitus. 7. Define dropsy. Name four diseases which it accompanies. Given a disease producing it, how would you treat dropsy? 8. Name some of the common forms of tuberculosis. Give a modern treatment for pulmonary tuberculosis.

South Carolina June Report

Dr. A. Earle Boozer, secretary of the State Board of Medical Examiners of South Carolina, reports the written examination held at Columbia, June 13-15, 1911. The number of subjects examined in was 17; total number of questions asked, 105; percentage required to pass, 75. The total number of *candidates examined was 124, of whom 97 passed, including* 2 osteopaths, and 27 failed, including 1 osteopath. Six candidates were licensed through reciprocity. The following colleges were represented.

A Handbook of Practical Treatment. By Many Writers. Edited by John H. Musser, M.D., LL.D., *Professor of Clinical Medicine in the University of Pennsylvania, Philadelphia*, and A. O. J. Kelly, A.M., M.D., Assistant Professor of Medicine in the University of Pennsylvania, Philadelphia. In Three Volumes. Vol. II. Cloth. Price, $6 net. Pp. 865, with 103 illustrations. Philadelphia: W. B. Saunders Co., 1911.

The second volume of this work includes a large number of articles on diseases of the circulatory system, infectious diseases, tropical diseases and animal parasites. The general excellence of the articles is conspicuous. The following are some of those requiring special notice: The principles of cardiac treatment are given by Clifford Allbutt in a short introduction of seven pages. The certainty given to some forms of drug medication is noted, and the fallacy of concluding that high blood-pressure means necessarily an increase of work for the heart, and a fall in pressure must need give the heart relief is pointed out. The danger to the heart from the slighter degrees of endocarditis is dwelt on and Allbutt advises to examine the heart of a child with even a slight cold every day. Myocarditis receives as much attention as pericarditis and endocarditis combined. Considerable space is devoted to a discussion of digitalis, squill, caffein and theobromin. The author expresses his belief that while squill is seldom necessary, this old cardiac remedy should not be allowed to fall into neglect. In some cases the prescription of 15 minims of tincture of squill may succeed when others of these capricious cardiac remedies have failed. Allbutt gives comparatively little credit to alcohol as a remedy in heart disease. In the treatment of dropsy, he finds that the exclusion of salt from the diet has not infrequently an astonishing success, but he is unable to define the conditions under which it succeeds. The hydropathic treatment and especially the Nauheim method are quite fully described. The surgery of the heart and artery is briefly discussed by C. T. Dent.

Typhoid fever is well treated by R. I. Cole. The subject of preventive inoculation is thoroughly discussed and the method advised. Considerable space is given to specific cure of the disease, as the author feels that this method may make possible the cure of all cases in the future. He takes a conservative position with reference to diet and expresses a decided preference for hydrotherapy over antipyretics. Pneumonia is discussed by H. A. Hare, who advocates the usual methods but warns against the abuse of strychnin and the employment of nitroglycerin, for the purpose of lowering arterial pressure. The treatment of exanthematous diseases is described by C. H. Weaver. He gives a full account of the theoretical and practical aspects of the antitoxin treatment. Intubation and tracheotomy are described in a well-illustrated article by J. H. Jopson. In accordance with its importance, tuberculosis occupies a considerable section of the book, something more than 100 pages. The article is by E. O. Otis. The hygienic methods and the details of open-air treatment are fully given with abundant illustrations. The same is true of the construction of sanatoriums and methods of sanatorium treatment. The author reviews the various specific and medicinal forms of treatment, but in conclusion emphasizes the immense superiority of the hygienic-dietetic measures. Syphilis is treated by J. W. White and A. C. Wood. Gonococcic infection is well treated by E. Martin. Vaccinia, variola and chicken-pox are discussed by J. F. Schamberg. Cerebrospinal fever, cholera and plague are considered by L. F. Barker. In the treatment of cerebrospinal fever the author makes several suggestions, such as the injection of normal serum suggested by Hektoen and a modification of Bier's hyperemia as worthy of trial when Flexner's serum cannot be obtained. The rest of the book is occupied with the treatment of various infectious diseases by a number of authors whose work is excellent, but which is impracticable to mention separately.

The reading of this volume strengthens the impressions given by the first that we have a satisfactory presentation of the resources of the modern physician which ought to be a valuable guide to the practitioner in his daily work.

Pathologic Technic. A Practical Manual for Workers in Pathologic Histology and Bacteriology, Including Directions for the Performance of Autopsies and for Clinical Diagnosis by Laboratory Methods. By Frank Burr Mallory, A.M., M.D., Associate Professor of Pathology, Harvard University Medical School, and James Homer Wright, A.M., M.D., S.D., Director of the Pathological Laboratory of the Massachusetts General Hospital. Fifth Edition. Cloth. Price, $3. Pp. 507, with 162 illustrations. Philadelphia: W. B. Saunders Co., 1911.

The revision of this edition seems to be a thorough one, and a number of new methods of practical value have been introduced. The methods of obtaining the opsonic index, however, are not given. The Wassermann technic is described, but not a word is said about the tuberculin reaction, which one would expect would be described in a book that claims to give directions for clinical diagnosis by laboratory methods. No reference is made to blastomycosis or oidiomycosis; an illustration or two of the characteristic organisms would be helpful, and the same is true of sporotrichosis. One is also surprised that no mention is made of the appearance of pneumococcal and streptococcal colonies on blood-agar. In the next edition the references should be given according to some uniform method and standard abbreviations should be used.

The Bellevue Hospital Nomenclature of Diseases and Conditions with Rules for the Recording and Filing of Histories. Compiled by the Committee on Clinical Records Composed of Drs. Robert J. Carlisle, Warren Coleman, Thomas A. Smith and Edmund L. Dow. Revised and Made to Conform to the International Classification, 1911. Morocco. Pp. 327. [General Medical Superintendent, Bellevue Hospital, First Avenue and 26th Street, New York City.]

The nomenclature of diseases compiled by the committee on clinical records of Bellevue Hospital is too well known to students of vital statistics to require any description. The present edition is conveniently and substantially prepared, being in the form of a small volume with flexible leather covers which can be carried easily in the pocket. The work was published first in 1903 and revised in 1909; the present edition has been collated with the international list of causes of death, while the orthography conforms to the Basel nomenclature endorsed by the Committee on Nomenclature of the American Medical Association. Until such time as we have a single, official and universally observed system of nomenclature, the Bellevue Hospital system will be of great value and will, doubtless, have many followers.

Die epidemische Kinderlähmung (Heine-Medinsche Krankheit). Von Dr. Paul H. Römer, Abteilungsvorsteher am Institut für Hygiene und experimentelle Therapie in Marburg. Paper. Price, 10 marks. Pp. 256, with 57 illustrations. Berlin: Julius Springer, 1911.

This work will be welcomed by those interested in poliomyelitis, especially in its epidemic manifestations. It contains, in addition to the author's own well-known researches, during the epidemic of 1909 in Marburg, into the transmission of the disease to monkeys, studies in immunity, etc., a complete exposition of the whole subject from a historical, clinical, pathologic, pathogenic and therapeutic point, up to the very latest work of Flexner and Clark in this country. It deals as fully with the future, the great unsolved problems, as with that which is known. The illustrations showing monkeys to which the disease has been transmitted, and also the histology of the disease, are excellent. At this time when laymen are as interested as physicians in this mysterious disease that has seemed, at least, to have taken on new characteristics in the last decade, this little volume should find a welcome place.

Minnesota Mushrooms. Booklet IV of Minnesota Plant Studies, of University of Minnesota, Minneapolis. By Frederic E. Clements, Professor of Botany and State Botanist. Paper. Price, 50 cents. Pp. 169, with 124 illustrations.

This creditable piece of work, elaborately illustrated—partly in colors—gives rules for collecting, preparing and cooking. Particular instructions are given for recognition of poisonous specimens. The preface calls attention to the enormous annual crop, now almost wasted, either through fear or neglect. Probably the total value of mushroom crop of the state is nearly a million dollars. The pamphlet is interesting, practical and valuable. It may not particularly reduce the cost of living but it will enable many people to enjoy this easily obtained food.

Medicolegal

Construction of Statute as to Privileged Communications and Waivers of Privilege, Especially as Between Several Physicians

(Missouri & North Arkansas Railroad Co. vs. Daniels (Ark.), 136 S. W. R. 651.)

The Supreme Court of Arkansas favors a liberal construction of the statute of that state which provides that "no person authorized to practice physic or surgery, and no trained nurse, shall be compelled to disclose any information which he may have acquired from his patient while attending him in a professional character and which information was necessary to enable him to prescribe as a physician or to act for him as a surgeon or trained nurse." The court says that this enactment was manifestly made for the benefit of the patient. Its evident purpose was to throw around him a protecting shield so that he might freely and fully disclose to his physician every fact relative to his ailment with the confident knowledge that the information thus obtained could not be divulged to his injury or disgrace. Being for his benefit, the provision was adopted out of reasons of public policy as a privilege accorded solely to the patient; and, like any other privilege, it is one that the patient may waive.

By the terms of this statute, a physician is prohibited from disclosing information obtained while treating his patient, but it has been uniformly held by the courts of those jurisdictions having similar statutes that the provisions thereof must receive that construction which was intended by the legislature which framed them; and that is that the patient himself may waive the privilege of the statute in order to obtain the benefit of the physician's evidence. When this privilege is waived as to any particular witness, the opposing side is entitled to the benefit of the waiver as to such witness. But the benefit of such waiver in behalf of the adversary should not extend further than to the witness who has been called by the patient, or as to other physicians who may have been present on the same occasion to which the witness testifies.

By virtue of the statute the patient is alone given the right to remove the ban of secrecy. The patient may be willing to waive the objection of incompetency as to a particular physician in whom he reposes confidence, and yet be unwilling to waive this objection as to another, who treated him at a different time for the trouble complained of. The statute affords him this privilege, when the testimony of the offered witness does not relate to the same occasion as that from which the patient has removed the seal of secrecy.

When a patient divulges what occurred between himself and a certain physician who treated him, that would waive his privilege regarding a disclosure of all that such physician knew and all that occurred at the time that such physician treated the patient; but that would not authorize the opposing side to call another physician who might have treated the patient at another and different time for the same disease. So the court is of the opinion that the plaintiff, by the introduction of the testimony of a physician relative to his treatment of her after her injury, did not waive her privilege to object to the testimony of other physicians who had treated her prior to that time, although for the same alleged trouble.

Nor does the court consider that there was a waiver of privilege when the plaintiff was asked, on cross-examination, if the physicians whom the defendant company desired to introduce as witnesses as to her condition prior to her alleged injury had not treated her for displacement of the womb, and she denied it. The company urged that it was entitled to have the benefit of those physicians' testimony in order to contradict the plaintiff. But, if the defendant's position in that respect should be upheld, then the above statute in regard to privileged communications would be easily evaded. In any cause where the opposing party desired to obtain the testimony of an attending physician, it could be secured in like manner, although against the objection of the patient. The plain provisions of the statute forbidding such testimony by a physician cannot thus be abrogated.

Liability for Results of Bruise Followed by Cancer

(Louisville Railway Co. vs. Steubing's Administrator (Ky.), 136 S. W. R. 634)

The Court of Appeals of Kentucky affirms a judgment for $7,500 damages against the railway company for injuries sustained by Mrs. Steubing in being thrown from one of the defendant's cars as she was about to alight from it. A sudden start was alleged to have thrown her from the platform to the ground. She was a large woman. The handle of an umbrella which she had in her hand bruised her breast as she fell on the ground. She thought at the time that she was not hurt, and said so, but soon found that she was worse hurt than she supposed, and was under a physician from the time of the accident and suffered very greatly. Within six months after the accident, a tumor appeared on her breast at the point where it was bruised by the umbrella handle. It was then about as large as an English walnut, and the physician advised her to have an operation performed, but that she did not do, and about a year after that she returned to the physician, who told her that she must have the operation performed at once. The tumor had then developed into a cancer of the breast. The operation was performed, but she died not long afterward.

It was earnestly insisted that all the evidence as to the cancer should have been excluded from the jury, as it was not shown that that was the direct and proximate result of the injury. That, however, the court answers by saying that the testimony of the physicians introduced on behalf of the plaintiff was to the effect that 15 per cent. of cases of cancer of the breast may be traced back to a traumatic injury; that the cause of cancer is unknown, and that it is not known that the injury in these cases was the cause of the cancer. But the physicians gave it as their opinion that in a glandular structure like the breast, where the circulation is very extensive, there are what are called embryonic cells, and that a bruise would start an embryonic cell to growing and develop into a growth different from the original growth; that falling from a street car, and having an umbrella punched into her breast, would be a sufficient or probable cause for the condition in which they found her; that the injury would not cause the cancer, but it might bring about a condition which would result in it when a cancer would not have otherwise existed; that any chronic inflammatory condition in the breast was liable to bring about such a condition, and that a great per cent. of the tumors of the breast in women took on at some time malignancy. These physicians stated facts sustaining the view which they advanced, and the defendant offered no contradictory evidence. The proof for the plaintiff was to the effect that Mrs. Steubing was a strong, healthy woman, without an ache or a pain until her injury; that after that she was never without pain, and the severity of her sufferings, as well as their constancy, tended strongly to confirm the conclusion of the physicians that the malignant cancer was the result of the bruised condition of the breast which she received in the fall. At any rate, there was sufficient evidence on that point to go to the jury.

Liability of Masseurs for Practice of Medicine—When Law Took Effect

(Dankworth vs. State (Tex.), 136 S. W. R. 788)

The Court of Criminal Appeals of Texas affirms a conviction of the defendant Dankworth of unlawfully practicing medicine. He claimed to be a masseur. The state's witness testified that he took his wife, who was suffering with some female disease, to see the defendant, and he said he could cure her. He said that she needed a wash for use at home, and said that he would call at the drug store and have it put up, which was done. He treated her at his home, and charged $20. The court says that, under its holdings that those who, for pay, practice massage for the cure of disease, practice medicine, it became immaterial whether or not a charge was made for the prescription at the drug store.

The jury was instructed that the provisions of the medical practice act of 1907 do not apply to masseurs in their particular sphere of labor, who publicly represent themselves as such; but a masseur is not permitted under the law to treat, or offer to treat, diseases or disorders, mental or physical, or to effect cures thereof, and charge therefor, directly or indirectly, money or other compensation. This charge was in accordance with the decisions of this court.

It was insisted that the medical practice act approved April 17, 1907, did not become effective until one year and ninety days after the adjournment of the legislature, on April 12, 1907; but the court does not think that such contention was the proper or legitimate conclusion to be placed on the act. The act itself became effective within ninety days after the adjournment of the legislature—on the 12th day of July, 1907. In the act, in Section 6, it is provided: "Within one year after the passage of this act all legal practitioners of medicine in this state, who, practicing under the provisions of previous laws, or under diplomas of a reputable and legal college of medicine, have not already received license from a state medical examining board of this state, shall present to the Board of Medical Examiners for the State of Texas documents, or legally certified transcripts of documents, sufficient to establish the existence and validity of such diplomas or of the valid and existing license heretofore issued by previous examining boards of this state, or exemption existing under any law," etc. Laws in force prior to the passage of that act required the diploma or license of a physician to be filed and recorded in the office of the clerk of the district court in the county in which one proposed to practice, and inasmuch as the defendant testified that he never filed in any county a license to practice medicine, the exceptions in the act could not avail him. If he had held a diploma from a reputable or legal college of medicine, or a license issued by previous examining board, it would have been a matter peculiarly within his knowledge, and if he had relied on that as a defense he should have made that proof.

Action for Malpractice Barred by Statute of Limitations

(Lotten vs. O'Brien (Wis.), 131 N. W. R. 361)

The Supreme Court of Wisconsin reverses a judgment obtained by the plaintiff and directs that the complaint be dismissed because it holds that the alleged right of action for malpractice was barred when the action therefor was commenced on November 13, 1909. The court says that the complaint charged that on August 24, 1908, the plaintiff employed the defendant to set, etc., a broken arm. It appeared that the acts of negligence complained of took place not later than September 26, 1908, when the treatments by the defendant ceased. The mere fact that there was no discharge of the defendant on that date would not change this result. The statute of limitations began to run when the cause of action accrued and this accrued when the negligent acts were committed, without reference to the time of discharge. The real negligent act which caused the injury to the plaintiff was the improper setting of the bones in his arm. The negligent omission to discover this occurred at such dates and times as the defendant undertook to examine, treat, and care for the disabled arm. At that time the Wisconsin statute of limitations applicable was one of one year, and the limitation of one year having begun to run when the two-year act of 1909 went into effect, and the latter act providing a new period of limitation, the former limitation statute was continued in effect as to such former acts under Wisconsin law.

A Physician Cannot Testify as to Examination Made to Aid Compromise

(Woodward vs. Southern Railway Co. (S. C.), 70 S. E. R. 1060)

The Supreme Court of South Carolina holds that, there being evidence that the plaintiff's counsel and an agent for the defendant entered into negotiations looking to a compromise settlement of the plaintiff's claim, for personal injuries, and that, in the course of these negotiations, and in furtherance of them, it was agreed that a certain physician should make an examination of the plaintiff, to ascertain the extent of his injuries, evidence of disclosures made by either party to the other, directly or indirectly, in negotiations for a compromise, not being admissible, testimony of the physician as to the examination was properly excluded.

AMERICAN

Titles marked with an asterisk (*) are abstracted below.

Journal of Infectious Diseases, Chicago

September

1 *Local Production of Antibodies. L. Hektoen, Chicago.
2 *Resistance of Tubercle Bacilli to Dry Heat. C. Krumwiede, New York.
3 Effect on Protoplasm of Nitella of Various Chemical Substances and of Microorganism Introduced into the Cavity of Living Cell. M. A. Barber, Kansas City.
4 *Antistreptococcus Serum. G. H. Weaver and R. Tunnicliff, Chicago.
5 Studies on Chemistry of Anaphylaxis. Experiments with Isolated Proteins, Especially Those of the Hen's Egg. H. G. Wells, Chicago.
6 *Bactericidal Action of Quinone and Other Phenol Oxidation Products as Determined by Rideal-Walker Method. W. Thalhimer and B. Palmer, Charlottesville, Va.
7 Pneumococcus Anaphylaxis and Immunity. E. C. Rosenow, Chicago.

1. **Local Production of Antibodies.**—The results obtained from experiments by Hektoen do not point to any local production of specific antibodies in dogs injected with goat or rat corpuscles, at least not so far as concerns the tissues about the anterior chamber of the eye, the tissues of the pleura, and the subcutaneous tissues.

2. **Resistance of Tubercle Bacilli to Dry Heat.**—Krumwiede found that air-dried tubercle bacilli are many times more resistant to dry heat than are bacilli heated in fluids or steam.

4. **Antistreptococcus Serum.**—Antistreptococcus serums were found by Weaver and Tunnicliff to lose their opsonic power rapidly, which may for some time be largely restored by the addition of fresh human or guinea-pig serum. Guinea-pigs may be protected against virulent cultures of streptococci by previous injection of antistreptococcus serums. The protective power of immune serums continues so long as they can be reactivated by fresh serum. Injections of immune serums in guinea-pigs may be followed by increased activity of leukocytes of short duration and by an increased opsonic power for streptococci in the blood-serum persisting for about ten days. The immunity in guinea-pigs produced by injection of immune serum persists for about eight days. Of three fresh commercial serums manufactured in the United States which were tested, two were active and one inactive. The two European serums were active. Fresh normal human serum and fresh human serum from persons infected with streptococci are able to reactivate antistreptococcus serums. This indicates that such serums may have some protective and curative effect in man in cases of streptococcus infections. The specific antistreptococcus bodies are resistant to heat and chemicals (trikresol, 0.4 per cent. chloroform) and are closely associated with the pseudoglobulins of the immune serum. The authors stated that it would be desirable to have some guarantee of the activity of antistreptococcus serums offered for sale.

6. **Bactericidal Action of Quinone.**—Thalhimer and Palmer found quinone the most efficient bactericidal substance yet reported; phenol-quinone is less active than quinone, and hydroquinone still less so. They emphasize that many of the commonly-used disinfectants and antiseptics, such as bichlorid of mercury, formaldehyd. argyrol, protargol, etc., are relatively inefficient in strengths used. Iodin, alcohol in strengths above 50 per cent., and silver nitrate in solution of 1-1,000 are very efficient bactericidal agents. Potassium cyanid and hydrocyanic acid, although powerful organic poisons, have a weak bactericidal action. The phenol coefficient of crude phenol is 4, of trikresol is 2.2 and of parakresol is 2.8, thereby disproving the statement that a combination of all three cresols is more powerful than any one of them. Beta-naphtol and sodium hydroxid neutralize one another's bactericidal action, and this would also occur in the intestine and so render the former substance useless as an intestinal antiseptic. The work of recent observers and the authors' results indicates the advantage of getting away from the use of bichlorid in surgical technic and the substitution for it of tincture of iodin and 50 per cent. alcohol.

12 Puerperal Infections. J. O. Polak, Brooklyn.
13 *Radical Treatment of Pelvic Inflammation. E. P. Davis, Philadelphia.
14 Strangulated Inguinal Hernia in the Female. H. A. Royster, Raleigh, N. C.
15 Treatment of Breast Cancer. T. Abbe, Washington, D. C.

8. Abstracted in The Journal, July 8, 1911, p. 162.

9. **Hydatid Mole.**—Of Vineberg's three cases following hydatid mole, two patients were operated on four years ago; one patient is in good health at the present time; the other was lost sight of shortly after leaving the hospital, when he was fully convalesced. The third patient was operated on five months ago. A couple of weeks after her discharge from the hospital, a small bleeding growth appeared in the vaginal scar. Suspecting a recurrence Vineberg excised it but the pathologist could not detect any evidence of chorioepithelioma in it. She is in excellent health, and the vaginal vault is smooth and perfectly healed.

13. **Treatment of Pelvic Inflammation.**—It is emphasized by Polak that curettage, douches and examinations during the acute stage of puerperal infection, break down natural barriers and open avenues for further dissemination of sepsis to the myometrium, parametrium and adjacent tissues, and that the danger from curettage increases as the period of pregnancy advances. The endometrium should never be curetted in acute streptococci infection, neither should the placental site ever be curetted. Instrumental evacuation of the uterus should be limited to pregnancy of eight weeks or under: digital exploration and digital curettage is the most rational method of learning the contents of the uterus. After the uterus is once thoroughly emptied, the pelvis should be left absolutely alone, except for postural drainage, and we should make every effort to support the patient and increase her natural blood resistance. If the blood-stream is sterile, and the blood shows a leukocytic resistance to the infection by a relative white cell increase, the prognosis is favorable, it matters not what form of cocci are found within the uterine cavity. Polak says, never disturb a local exudative focus postpartum, as long as the patient shows signs of improvement, unless there is definite evidence of a localized collection of pus, this should be opened by extra-peritoneal incision. Exudative pelvic peritonitis may be considered as a sequel of untreated or badly treated endometritis.

Thrombophlebitis is a conservative process on the part of nature, and manipulation or examination tends to break off infected emboli, and disseminate the infection to the remote parts of the body. Nature is competent in the majority of cases to localize and circumscribe the infection. Enormous pelvic and abdominal exudates may disappear without operation, and in time enlarged ovaries, tubes, etc., assume their proper size and function, and as long as the patient's general condition improves, no surgery is advisable. All operations are attended with less risk after the acute stage of the infection has subsided, and an exact diagnosis is more easily made at this time; and finally, vaccines have a definite field and are valuable adjuncts to the therapeutics of puerperal infection.

20 Treatment of Malaria by Salvarsan. M. A. Reasoner, U. S. A.
21 Dislocation of Malar Bone. R. P. O'Connor, U. S. A.
22 Chronic Interstitial Nephritis with Very Obscure Symptoms. G. B. Tuttle, U. S. A.
23 Miscellaneous Notes. R. C. Matson, Portland, Ore., and M. A. Reasoner, U. S. A.
24 Experiments Undertaken to Test Efficacy of Ipecac Treatment of Dysentery. E. B. Vedder, U. S. A.

19. **Lime Salts for Troops.**—The use of calcium lactate and permanganate is held by de Niedman to be particularly desirable during active campaigning under circumstances where the soldiers have to use drinking-water from questionable sources. He is satisfied that calcium permanganate added in definite quantities to drinking-water would act as a prophylactic and would prevent contracting dysentery and other enteric fevers, while calcium lactate, taken with food, would replace the deficiencies of lime salts in the various articles of the diet, thereby minimizing the tendency to the numerous inflammatory intestinal troubles often met and which cannot be rightly traced to careless preparation of food, or to drinking-water. It is his opinion that the routine use of lime salts under certain conditions would be of great benefit to troops serving for a prolonged period in the field or in the tropics.

Mississippi Medical Monthly, Vicksburg

September

25 *Treatment of Appendicitis by Hypodermic Injection of Colon Bacteria. H. M. Folkes, Biloxi.
26 Drops in Syphilis. H. L. Walker, Hot Springs, Ark.
27 Acute Enteritis. W. H. Frizell, Brookhaven.
28 Intestinal Obstruction Due to Intussusception and Volvulus. J. C. Walker, Houlka.
29 Medical Treatment of Appendicitis. J. W. Jordan, Lexington.

25. **Treatment of Appendicitis.**—Thinking that possibly the infection in a case of appendicitis was due to colon bacilli, and not being permitted to operate, Folkes concluded to try an injection of colon bacteria which he did by giving 200,000,000. Within twenty-four hours the temperature had gone to normal, pulse 102, facial expression natural, patient comfortable. The tumor, *pari passu*, became smaller and smaller and ten days after the injection had entirely disappeared. The patient is as well as ever.

36 *Case of Automatic Shedding of Gall-Bladder. H. G. Welsh, Hutchison.

36. **Automatic Shedding of Gall-Bladder.**—On the basis of a diagnosis of appendicitis Welsh opened the abdomen in the region of the appendix and found a good-sized abscess well walled off. The patient was in such an extreme condition that he decided not to remove the appendix as it appeared to be well covered up with adhesions, so he packed the abscess cavity with gauze and hurried the patient to bed, and ordered normal salt solution per rectum. The patient had only a slight rise in temperature at the time he entered the hospital and this did not change much for several days, running from ½ to 1½ degrees above normal. The patient began to improve, however, the gauze drain being removed on the fourth day, and replaced with smaller gauze packing each day thereafter. On the fifth or sixth day a fecal fistula developed and bowel contents discharged freely for a few days and then healed. About the fourteenth day after operation, a black object appeared in the wound at the morning dressing and looked very much as though it was a portion of gangrenous gut. The patient was improving daily, was much stronger and Welsh did not think the substance was bowel, although it looked and felt like it. When the gauze was pulled out of the wound the mass came out with it, and at first sight it looked like a piece of gangrenous gut about 5 inches long by 2 inches in diameter, with an opening at the smaller end, and about half full of a semi-solid or mushy contents. It was the whole gall-bladder. Two or three days after the shedding of the gall-bladder, bile began to discharge freely through the wound and did so for several days, and then ceased and the wound gradually healed. No gall-stones were found at the operation, and none passed through the wound afterward.

40. **Organic Matter in Expired Breath.**—Through the reaction of anaphylaxis the presence of organic matter was demonstrated in the expired breath by Rosenau and Amoss. In brief the method consisted in condensing moisture from the expired breath of man and injecting the liquid so obtained into guinea-pigs. After a suitable interval (at least two weeks) the guinea-pigs were injected with normal human blood-serum. Ninety-nine guinea-pigs were thus tested in twenty-five different experiments; of the ninety-nine, twenty-six gave definite symptoms of anaphylaxis; this does not include the animals showing suggestive or mild symptoms; in four the reaction was so severe that death ensued from anaphylactic shock. The expired breath of eight persons was tested; of these five gave positive reactions; on each of the remaining three, only one experiment was made. This organic matter must, according to the interpretations of our knowledge of anaphylaxis in the guinea-pig, be protein in nature. Guinea-pigs may be sensitized only with protein substances higher in the scale (that is, more complex) than the peptones. Further, this protein substance is specific and for the present it is assumed to come from the blood. The indications are that this organic matter is probably present in variable amounts, although the reaction is a qualitative and not a quantitative test.

The logical conclusion at which the authors arrive is that protein substances may be volatile. It seems unlikely that such a complex molecule should possess the power of passing into the air in a gaseous form. The volatility, however, now in question may resemble that solubility which deals with particles in suspension in a physico-chemical state (colloidal suspension). The protein may simply be carried over in "solution" in the watery vapor. The fact that organic matter is present in the expired breath does not mean that these substances are poisonous. It is evident, however, that the air contains many substances which we cannot at present discern, some of which may have an important bearing on health. Thus it is well known that most of the cases of sudden death following the first injection of horse-serum (diphtheria antitoxin) occur in adults. Children rarely give a severe immediate reaction at the first injection. How the adults become sensitized has always been a mystery. It may now be assumed that some susceptible persons may absorb, through the lungs, enough horse protein, from close association with horses to become sensitized. The fact that the expired breath contains definite amounts of specific organic substances will also have an immediate bearing on the problems of ventilation and the effects of vitiated air.

41. **Primary Intimal Arteritis.**—The authors maintain that total occlusion of vessels having a complete anatomic structure does result from the simple proliferation of the intima. Syphilis must be recognized as one of the factors potent to induce this lesion. Although nourishment for the inner layers of the media may be derived from the circulating blood in the lumen of the vessel, their preparations showed that such a method of nutrition is by no means necessary. In occlusion taking place in this manner, endothelial proliferation is primary, this being followed by subendothelial fibrous tissue hyperplasia. The vascularization of this proliferated tissue takes place by the growth inward of vessels from the adventitia. Necrosis in syphilis results both by the formation of tubercle-like nodules by the proliferation of cells with breaking down in the center, and also as the result of obliteration of vessels as the result of an intimal proliferation.

42. **Rapid Isolation of Bacilli.**—The modified Endomedium used by Kendall and Day contains 15 gm. of agar per liter instead of 40 gm. The colonies developing in 15 gm. agar are much larger in eighteen hours than those similarly grown in 40 gm. agar. The colonies are also more distinct. The reaction of the agar is made just alkaline to litmus, instead of being strongly alkaline to it; consequently those bacteria-forming acid bring about their characteristic changes very promptly because there is less alkali to be neutralized before the acid can assert itself. After eighteen hours' incubation on the medium modified as above, suspicious colonies are removed entire to small tubes containing 1 c.c. of sterile sugar-free broth, which has been kept at 37 C. previous to use and incubated in them at 37 C. for two hours. While the incubation is taking place, the sera are diluted ready for use. The cultures are then agglutinated with appropriate sera and watched for two hours. At the end of that time the results are reported. The whole procedure as outlined requires about twenty hours.

44. **Activity of Bacteria in Intestinal Tract.**—The cases studied on the Boston Floating Hospital during the summer of 1910 numbered thirty-nine. Nineteen patients died and twenty survived. Of those that died eight received *no sugar*; they were among the earliest studied, and it was from a study of the flora of this group that the ideas employed in the attempt to aid the others originated. Of those receiving sugar, and which died subsequently, two were on a modified milk diet previous to the use of lactose. One reacted very well both clinically and culturally to the sugar treatment, convalesced, and was doing very well on a milk modification. Finally she contracted a severe attack of acute bronchitis and had not strength enough to rally. Two patients died within three days of admission, too early to get the results of the lactose treatment, for the lactose was not given as a rule until after two or three days' starvation on sterile water. One patient was placed on lactose for eleven days, did very well, then on a milk mixture five days, still with improvement, then on Eiweiss milk. She died very shortly after. Two cases were pure Shiga bacillus infections, and terminated fatally rather promptly. This is the usual rule with pure Shiga infections, when the patients are seen as late in the disease as were many of those at the hospital last summer. Of the remainder one survived nine days on lactose, then died. The patient did not show the expected change in flora, and the question arises, were there vestiges of the fermentative flora to encourage? Obviously, if there were no fermentative organisms to start the new flora it could not develop. One patient died after twenty days' illness on the boat: six days of lactose, two of sterile water, then ten of lactose. The first two days were on sterile water. The last patient was placed on lactose solution for fourteen days, then on a milk mixture. She reacted very well bacterially, and no definite explanation of the cause of death can be advanced (syphilis?).

45. **Tuberculosis Among Ground Squirrels.**—Five cases of natural tubercle infection in ground squirrels have been observed. The gross pathology in these animals was as follows: Two had lesions of the lymph-glands alone, one of the lungs alone, one of the lungs and the omentum, and one of the liver alone. As compared with a human strain of the same age and number of generations, the growth on artificial media was far less luxuriant than that of the culture derived from man. The virulence of the squirrel cultures, judged by their effect on rabbits, agrees with that of the bovine type of *B. tuberculosis*.

49. Isolation of Bacillus Typhosus from Butter.—Altogether, eight samples of butter obtained from the institution were studied by Bergey and typhoid bacilli were found in one of the samples. The special agar media that seemed to be most helpful, in that it was possible to pick out the colonies of *B. typhosus* from amongst the colonies of other bacteria in the butter, were the Drigalski-Conradi agar and the malachite green agar. No typhoid organisms were recovered from the plates made with the endomedium. Bergey thinks that this result is probably due to the fact that the endomedium may not have been properly prepared, though four different batches of it were tried. These special agar media are rather difficult to make up, as the original descriptions are somewhat involved and the process is rather long. From the results obtained it is evident that these special media are of great value, under certain circumstances, for the recovery of *B. typhosus* from infected food materials. After the sample of butter which contained the typhoid bacilli had been in the ice-chest for several weeks it was impossible to isolate any additional typhoid bacilli from it. Whether this was due to the fact that the organisms had all died out or whether they were not uniformly distributed Bergey does not state.

50. Peptid-Splitting Enzyme in Woman's Milk.—Warfield found tryptophan present in the mixture of human milk and glycyltryptophan. This ferment is destroyed by heating the milk to 75-80 C. or above. When the specimen of milk is rendered faintly acid by the addition of either HNO_3 or HCl, there is no splitting of glycyltryptophan. Controls of untreated, normal milk and part of specimen treated, were always incubated for the same length of time. The controls were always positive for tryptophan.

57. Warmed Ether Vapor.—Seelig says we may rest content with the simple fact that a warmed vapor will not stay warmed unless it is held under pressure. We have been led astray in our reasoning by the sight of ice crystals on the ether mask, or frost on the nitrous oxid gas cylinder. Indeed, we have been led so far astray as to lose sight of one of the fundamental facts in the administration of anesthetics, namely, when ether is administered by the drop method, its rapid evaporation robs the surrounding atmosphere of latent heat, thus perceptibly cooling it. This cooled air can take up only a moderate amount of ether vapor by reason of the fact that it is cooled, and thus we are furnished with a safeguard against oversaturating the patient with ether. This physical fact it is, which has contributed so much towards making the open method of administering ether so safe and therefore so popular. If we bear in mind the rapidity with which vapors part with heat, we shall probably not concern ourselves much with securing special warming apparatus.

66. Agenesia of Corpus Callosum.—A very complete study was made by Archambault of the clinical history and postmortem findings of a case of agenesia of the corpus callosum. He says that in cases of so-called agenesia of the corpus callosum, we have to do merely with an abscess of the callosal commissure proper. In a considerable number of cases, fetal hydrocephalus is the underlying cause of this anomaly. This lesion may act either by destroying a large part of the periventricular callosal layer, or by determining ventricular symphysis which then interferes mechanically with the development of the callosal commissure. The occipito-frontal fasciculus simply represents, as Sachs originally maintained, a heterotopy of the corpus callosum. It does not exist in the normal cerebrum. The fornix is formed not only by fibers derived from the gyrus hippocampi but also by fibers which originate in the gyrus fornicatus and reach it by traversing the corpus callosum. The internal sagittal layer of the frontoparietal lobe, the reticular zone of Sachs, represents the corona radiata of the gyrus fornicatus or first limbic convolution. The anterior commissure probably enters into the constitution of the temporal segment of the tapetum. Aside from this possible element, the tapetum is formed exclusively by the fibers of the corpus callosum.

73 Protein Metabolism in Infants and Children. H. Schwarz, New York.
74 *Case of Infection of New-Born. L. Taylor-Jones, Washington, D. C.

70. Scaphocephalus with Retinal Changes.—The symptoms in the case cited by Fairbanks strongly point to an intracranial tumor. The classic general symptoms presenting themselves in a strikingly typical manner, headache, vomiting, optic neuritis and choked disks with retinal hemorrhage. The symptoms were so intense that the child was twice admitted to the hospital with a view to using a radical palliative decompression operation. The abnormal shape of the head was thought to be a congenital deformity, without connection with the active and serious clinical phenomena. Eye examination showed 2 mm. swelling of the disk and beginning signs of organization. It was thought that there was slightly less coordination and power in the right upper extremity than in the left, but this was always questionable. No other signs were present. His gait, even with his eyes closed, was excellent. From this time to the time of making this report (six months), he was perfectly well subjectively, and presented no abnormality, except the cranial deformity and the changes in the retina.

72. Albumin-Milk in Infant Feeding.—Grulee's report consists of thirty cases, of which twenty-five are of nutritional disturbances and five of parenteral affections. Of these cases, five were dyspepsias, with four recoveries and one failure; seventeen were decompositions, with two failures and three deaths. Of those classified as failures, both were cases which could not be controlled. Of the deaths, one was the first infant on which the albumin-milk was used and the albumin-milk period was preceded by a long period of decline; one death resulted from erysipelas. In one case of intoxication the infant made a beautiful recovery. In this case a modification of the albumin-milk was used. Instead of suspending the curds in the buttermilk, barley-water was used, and this in turn gradually replaced, 1 ounce or 2 ounces at a time, with buttermilk. In this case the above procedure did good service. One of the cases in this series was an infant a few days old, of comparatively good health, which thrived well on the food. Another case, aside from a rather severe rickets and furunculosis of the scalp, showed no disturbance and yet went steadily down hill and died a month or six weeks after leaving the hospital.

Of the five cases of parenteral affections, three infants died, one was but slightly improved, while one made an excellent recovery. One of those which died had a very severe anemia pseudoleukemica infantum, one was afflicted with subcutaneous abscesses which were very bad at the start and cleared up entirely for some days, then began again and during the second attack the child died. The third was a case of intestinal tuberculosis. The infant which improved only a little was one with syphilitic hydrocephalus; the other case was an ordinary case of congenital syphilis.

In the twenty-five instances of nutritional disorder there were eighteen recoveries, three failures and four deaths. Of the deaths, two only were uncomplicated nutritional disorders. Of the failures, no infant was on the albumin-milk longer than twelve days, one being taken off the food because of a rather alarming loss of weight in the first week. In no mild case in which it was thought that the infant would thrive on the usual milk mixtures was the albumin-milk given. This is shown by the fact that fifteen of the twenty-five cases were in infants 4 months or under. Quite interesting was the rapid fall and rise of the weight-curve. This occurred usually in more severe cases and often a drop of 4 to 5 ounces in twenty-four hours would be registered, with a quick return to a point above that before the drop.

74. **Infection of the New-Born.**—This baby, which had been apparently perfectly healthy for ten days of its life, died when 12 days old, of a streptococcus infection whose course was by the way of the umbilicus through the left hypogastric artery. At no time was there any sign other than perfect health at the navel. Taylor-Jones could not say when the infection occurred, but it would seem that the most reasonable presumption would put it at the time of, or soon after, the separation of the cord on the fourth day. The physiologic thrombus of the left hypogastric would probably not be broken down by sepsis for several days, and several more days might be required to have the circulation of the organisms in the blood show evidence by elevation of temperature and external signs. Taylor-Jones surmises that had it taken place at the time of birth, infection would probably have manifested itself several days earlier because of the organisms passing directly into the blood-current, before formation of the thrombus.

80. **Progress in Treatment of Chronic Joint Diseases.**—Reasons and data are given by Marshall to show how greater accuracy in diagnosis; greater skill in applying remedies accurately according to physiologic needs of the tissues; discoveries of new methods of treatment through development of many medical researches; improvements in surgical knowledge and skill; and more keen appreciation of the advantages of preventive measures will all favorably influence progress in treatment of chronic arthritis. Simultaneously with increase in efficiency of such treatments there will develop greater confidence among patients with regard to medical understanding of joint diseases, and this of itself will be an additional advantage, if existing practices that are so fatal to satisfactory results can be minimized, namely, the habit which patients have of wandering from one physician to another, trying indiscriminately many cures until hope of recovery has passed and their joints are worn out and damaged beyond repair while attempting to restore their normal function.

81. **Humidity and Health.**—The beneficence of moisture is emphasized by Goldsbury. He says that the problem of constructing buildings in such a way as to keep the interior up to a fair degree of humidity is a large one. So far engineers have made little practical progress toward its solution. Their ingenuity has been taxed to improve the moisture in large public buildings. The devices for this have so far proved too expensive for private dwellings, hotels, offices or schoolhouses. Another difficulty has been to arouse public opinion on the subject, or to convince of its importance. Americans complain of the drafty, poorly heated buildings abroad, but American houses are both too nearly air-tight and too much heated for ideal humidity. Too little of the moist fresh air enters; and this, under the rising temperature, has its relative humidity greatly lowered. The situation calls for some special measures.

Clothing and covering of the body interferes more or less with an equal shading of humidity and evaporation and circulation of the air directly over the skin. Advantage may be taken of this fact. If the skin is allowed to enjoy longer periods of freedom from clothing upon retiring or rising, or when they are being changed, the body will be bathed more equally by air of a like degree of humidity and should benefit from such baths. Clothing which permits freer circulation of air is a step in this direction, but this whole subject can be reserved to a later discussion. If one must live much indoors he may improve the temperature of his rooms by various devices, such as keeping growing plants and setting about porous dishes, as flower pots full of water. If such receptacles are set near electric fans the stirring of the air facilitates evaporation. Some housekeepers have even placed such pots within the radiator.

There are some objections to the use of plants, such as the amount of care they require, the space they occupy and the physiologic effects of their odors and gaseous exhalations. Those who love plants, however, may get encouragement from the fact that the beauty and fragrance are joined with a humbler and inconspicuous but very much needed service. Porous vessels, too, demand some care. If they are not covered dust will gather within them, evaporation will be retarded and the water itself will grow foul. The vessels should be covered or closed and the water changed occasionally to keep all fresh. As with plants, the esthetic sense may be satisfied along with the useful. Pottery may be formed to furnish an elaborate amount of evaporating surface and at the same time artistically designed.

Goldsbury says that there is nothing for humidity like the out-of-doors. Even though the humidity may range from that of parched Arizona to that of the English Channel, it is so admirably adjusted to the environment on nature's gigantic scale, and so likely under the vast majority of conditions to be superior to anything that can be produced artificially, and it is so bound up with advantages of other sorts, that the Great Open must be the common refuge, and to the natural we must turn in our search after the ideal. Conditions indoors may and must be improved; conditions outdoors wait to be enjoyed.

85. **Bronchiectasis and Abscess of Lung.**—From sixteen cases of abscess which he has seen, eight of which he has operated on, Robinson has come to prefer the responsibility of finding the abscess rather than risk operation at that late stage when the patient's resistance has been lowered during prolonged observation and repeated negative explorations. Continued expectant treatment may result in a fetid empyema. Drainage of such empyemata in the presence of abscess is attended with high mortality. The operative mortality of uncomplicated acute abscess should be less than 8 per cent. in cases which have not been delayed by lack of diagnosis or prolonged observation. He says that exploration for deep

abscess, in the complete absence of adhesions, is more safely performed under differential pressure, the use of which, to say the least, increases confidence. Furthermore, many recent experimental investigations have bettered the technic of opening and closing the chest, and a negative exploration should be devoid of complications.

Operative infection of normal pleura, and postoperative pneumothorax should, nevertheless, be avoided in every possible instance. A careful search before and during operation for an area where adhesions are present will prevent the opening of the free plural cavity. In his six cases of acute abscess, Robinson has established drainage with no mortality.

95. **Vaccine Treatment and Prevention of Sepsis.**—The cure employed by Duncan consists in giving the patient crude pus from his own wound by the mouth. The prevention is effected by putting the discharge from a fresh wound in the patient's own mouth. To get some idea of the possibilities of this method of curing and preventing infections, he directs attention to the dog and cat and other animals that lick and cure their wounds. He says this is the oldest method of wound treatment the world has known, for animals have always licked and cured their own wounds. The only place where, as a rule, a cat or dog has bad infections is on the head, which it is impossible for them to lick. If the pus from their head wounds is placed in the mouth they will recover from their head wounds as they do from wounds which they can lick. In licking their wounds, they place the autogenous vaccine in healthy tissues away from the seat of disease, and develop specific antibodies in the serum. This is Nature's method of curing an infection. It is the simplest and the best method of curing infection.

1. See The Journal, Sept. 9, 1911, (12) 930.

2. **Transmission of Leprosy.**—The possibility of the bacillus being carried by vermin occurred to Long. With a view to testing this hypothesis, bed-bugs obtained from huts which had never been inhabited by lepers were caused to bite lepers in the neighborhood of leprous nodules on the face. The bugs were then killed and the alimentary tract and its contents examined. In every bug that bit freely a bacillus was found which in shape, size and staining reactions is similar to the *Bacillus lepræ*. Control bugs from the same hut gave in every instance a negative result. The experiments are still in progress.

5. **Tuberculous Peritonitis.**—Statistics on tuberculous peritonitis in children quoted by Rolleston are the following: Faludi has drawn up tables showing the percentages of cures in parallel series of cases of tuberculous peritonitis in children operated on and not operated on. The authors he quotes are Cassel, Monti, Pic, Schmitz, Schramm and Sutherland, who all give parallel series of cases operated on and not operated on. The divergence in these statistics is considerable. Schramm found 80 per cent. of cures among the operated patients and 64 per cent. among the non-operated; Pic observed recovery in 74 per cent. of the operated patients and in 5 per cent. only of the nonoperated; Wutherland observed recovery in 50 per cent. of the operated patients and in 81 per cent. of the nonoperated. By adding up all the operated patients we get eighty-eight cures, or 70.4 per cent., in 125 cases, as contrasted with fifty-one cures, or 33 per cent., in 156 patients not operated on. The question of operation on ascitic patients may be fairly summed up in the statement that it should be tried after hygienic and medical treatment has been given a fair trial for a month or so without any definite benefit. Simple paracentesis is not often necessary and is seldom practiced. After removal of some of the fluid, injections of various kinds through a cannula have been employed; thus sterilized air, oxygen (Schulze), isotonic salt solution, epinephrin (adrenalin) (Wynter) have been reported to give good results. The injection of camphorated naphthol is a dangerous procedure (Guinard). Rolleston has no experience of any of these methods.

6. **Idem.**—As to the ultimate results of laparotomy in tuberculous peritonitis and its value as a means of treatment, Wright says that probably not much more than half the patients would live to grow up, for of those who recover for a time a large proportion die of tuberculosis in some form within a few years, though the immediate operative mortality is of course very small. There is no hard-and-fast line between ascitic and plastic cases, either as a matter of morbid anatomy or of operative treatment, or of mortality. But operation is simple in cases in which there is much fluid, and may

be impossible in obliterative cases. Tuberculous mesenteric glands may be safely removed, and in some cases certainly should be removed. The rôle of surgery in tuberculous peritonitis is rather to remove secondary troubles, such as obstruction, and to get rid of noxious collections of fluid and local foci of tubercle, rather than to play any great part in the prevention or cure of the disease as a whole.

7. *Edema Following Gastro-Enteritis in Children.*—Hume's attention was first turned to a group of cases of general edema following gastro-enteritis in 1908, when he had four patients under his care in the children's ward of the Royal Victoria Infirmary at the same time. He could not find any evidence of heart or kidney disease in any of these. Since November, 1908, he has seen nine similar cases; three of these have been under his care at the Royal Victoria Infirmary and six under the care of another. Hume has failed to discover that there is any difference between the salt exchange in cases suffering from this variety of edema and that which takes place in perfectly normal children. He does not think that the theory of salt retention wholly explains the condition any more than it does in all cases of edema in Bright's disease. From the fact that the vascular conditions were *improved by the injection of epinephrin, that the children* improved more rapidly under its administration than without it, and from the fact that in these two cases there was an abnormal degree of fibrosis in the medulla of the suprarenal gland, Hume suggests that attention in future be paid to these glands when opportunities of examining them occur. Finally, he refers to the fact that toxins are developed in the gastro-intestinal tract which cause degeneration and fibrosis of the suprarenal medulla, and that, either as the result of the absence of suprarenal secretion or from the direct action of the toxins on the capillary cells, the latter become more pervious to the outlet of fluid.

10. **Milk Feeding in Children After First Year.**—Vogt cites a number of instances to prove that many children may be injured by a liberal milk diet. The long-retained dogmatic belief of the medical profession that milk is not only the ideal food for infants, but for every age and every ailment, must be abandoned. The requirements which the food of the infant and that of the older child have to meet are quite different. The infant needs for the construction of his rapidly growing organism relatively large quantities of fluid, as well as of solid matter, to be retained as living substance. The older child and the adult, on the contrary, require above all, a supply of material which will furnish the amount of energy necessary to provide for the maintenance of the temperature of the body and the production of muscular work, both of which play only a minor part in the case of the infant. Again, milk lacks certain constituents which must be present in the food of adults and older children. It is extremely poor in iron, it is entirely lacking in purin bases, and last, but not least, it is for most people unappetizing. This last constitutes a very real defect for individuals who have passed their first year.

11. **Etiology of Nevi.**—From figures yielded by his investigation Fitzwilliams believes that females are affected more frequently than males, that nevi are almost always present at birth, and only comparatively few appear at a later date, spider marks and deeply seated nevi being the chief exceptions to this rule; that nevi most usually start on the surface, and less frequently in the deeper structures; that their extension and growth is intimately connected with the nerve supply of the part.

14. **Scoliosis.**—From a study of these 1,000 cases the following points are emphasized by Roth: 1. Scoliosis is a disease of females—843 females, 157 males. 2. Scoliosis is a disease of adolescence—86 per cent. between 6 and 20 years. *3. The frequent occurrence of scoliosis in members of the* same family points to hereditary transmission. 4. The bad position assumed in writing, a delicate constitution and too rapid growth are largely responsible for very many cases. 5. Difference in the length of the legs is not a common cause of scoliosis. 6. Pain is a frequent symptom. 7. Flat-foot is a very frequent complication. 8. Attention to dress before any treatment is absolutely essential. 9. Treatment should never be commenced until a record of the osseous deformity has been made. 10. Treatment by "posture and exercise" entirely arrests the increase of bony deformity in all but 5.5 per cent. of observed cases, and in 3.3 per cent. slightly decreases it. In 83 per cent. of cases a permanent practical cure is brought about.

16. **Hare-Lip.**—The modifications described by Goyder consist in: 1. Extensions of the Owen-Mirault flap. These result in a narrowing of the attached part of the lip without diminishing the effective length from corner to corner. 2. A vertical splitting of this flap. 3. The separation of a thick wedge-shaped ribbon of mucous membrane at the mucocutaneous junction on the side opposite to that on which the Owen flap is cut, leaving it attached by the red margin and dovetailing it into the split Owen's flap. This ribbon is enitrely removed in Owen's operation. This results in a greatly thickened red margin at the line of suture, which is not opposite to the end of the scar in the lip. It does not attract attention, nor does it become increasingly obvious as time goes on. 4. Special methods of dealing with the nostrils. Incise and separate the ala nasi at its junction with the *cheek. Reflect the nasal flap. Suture through alae nasi, the* nasal flap (if used), and back through septal side. Put a suture on the face to close the nostril in front. Deal with lip, remembering that its suture line must not be opposite to that in the nose.

17. **Treatment of Measles.**—Milne again calls attention to the so-called "pencil" infection in measles.

18. **Spinal Curvatures.**—Timberg describes eighteen exercises which he employs in correction of spinal curvatures.

20. **Breast-Feeding.**—It would appear from the authors' observations that those infants who are brought up in institutions and receive a larger amount of breast milk increase in weight more rapidly than those who attend infant consultations as out-patients; on the other hand, among this latter class of infants it would appear that those who receive larger quantities of milk, instead of putting on more weight per week put on a smaller amount. It may be that on an average the milk which is separated in large amounts is inferior in quality, and in this connection it must be remembered that chemical analysis only affords a very crude estimate of quality. Analysis may show the relative percentage of proteids, fats and sugars, but it cannot, as yet, afford a differential estimation of constituent protein bodies, nor does it indicate whether or not they possess toxic properties. On the other hand, it must be remembered that institutional infants live under superior hygienic conditions than do the poor class of infants who attend our consultations; *ceteris paribus*, the better the hygienic conditions and the more active the vital processes the greater is the demand for food. Want of air, sunlight and all the natural stimuli for active metabolism reduce the vitality of our out-patient infants to such a debased level that it is conceivable that an allowance of food which would be physiologically appropriate for the institu*tional infants may be relatively excessive for the needs of* our class of out-patient infant; and overfeeding, as is now well understood, leads sooner or later to malnutrition and loss of weight.

23. **Intussusception.**—The initial symptoms in Wood's case were vomiting and the passage of blood and mucus per anum. Pain was said not to be a marked feature at the onset. The

vomiting persisted periodically for a week, and blood was passed by the bowel for four or five days. Constipation was absolute throughout the illness, so that for a whole fortnight no fecal matter was voided. During the fortnight she apparently had frequent attacks of intestinal colic, but for the greater part of the time she lay in bed in a listless condition, until toward the end when pain became more frequent and more severe, and she then became restless. She took fluid nourishment well after the vomiting had ceased. The abdomen was noticed to swell progressively, particularly toward the end of the fortnight. Several enemata were given, and these were either retained or returned in part without force. There was never any fecal material in the washings, but occasionally some blood and mucus. The tongue was dry and clean; pulse 120 and fairly good, and temperature 99.6 F. The abdomen was uniformly and considerably distended. Peristalsis was not observed. Rigidity was absent and the abdomen was free from tenderness. There was too much distention to allow of any swelling to be palpated. The rectal examination was negative.

On opening the abdomen through a right paramedian incision it was impossible to prevent the prolapse of many coils of greatly distended bowel. An intussusception was easily delivered through the wound. It had traveled to the left iliac fossa. As is usual, the larger part was easily reduced, but the force employed in attempting the reduction of the last 6 inches or so was too great and the intussuscipiens gave way, the intussusceptum escaping through the rent. It was now seen that the intussusception commenced about 18 inches above the ileocolic valve. About 12 inches of the small gut, including the intussusception, were resected, and an end-to-end anastomosis rapidly made. The child's condition was critical, and as the suturing had to be rapidly carried out in edematous bowel the junction was almost certainly imperfect. For this reason, and also on account of the great intestinal distention, the bowel was drained on the proximal side of the junction by a Paul's tube. The abdominal wall was closed save in the lower part where the drainage was established. The patient recovered.

40 Obstetrical Anatomy of the Pelvis with Congenital Dislocation of the Hip Joint. (Recherches et conclusions nouvelles sur l'anatomie obstétricale du bassin à luxation coxo-fémorale congénitale double.) J. Delmas.

39. **Puerperal Psychoses.**—Picqué protests most vigorously against sending women with puerperal psychoses to an asylum, declaring that the mental trouble in these cases is merely a delirium accompanying puerperal septicemia. The infectious process may be mild or may cause no symptoms except this delirium, but the women are febrile deliriants and the delirium rises and falls with the rest of the infectious syndrome and does not survive it. He thinks that the importance of latent infection of uterine origin as a causal factor in mental disease does not receive the attention that it merits. His remarks apply only to the psychoses of the puerperium, not of the pregnancy. They may develop even without fever and the infectious process may be located elsewhere than in the uterus; surgical treatment of an infectious arthritis in a woman soon after delivery speedily cured the psychosis observed in one of his cases. An inherited taint is important in that women with it only need an opportunity for the delirium to develop, but an infectious process acting on the predisposition, especially when the infection is of a chronic character, may render the delirium incurable. Otherwise the prognosis depends on the curability of the underlying infectious process. The tardy melancholia of women after childbearing at which there has been no fever, is the result of some attenuated and latent infection, but if the infectious process has run along for a long time and become chronic there is danger that the melancholia may be chronic likewise. The importance of curing the focus at once is demonstrated by these views, which are based on wide clinical experience. He comments with dismay on the number of cases in which women with puerperal psychoses are sent to the asylum in his charge; it is not equipped for the local treatment necessary in these cases. On the other hand, the apyretics, with permanent mental disturbances developing sooner or later after the childbirth, belong in the asylums, as they require psychiatric treatment.

41. **Blood-Pressure in Acute Edema of the Lungs.**—Amblard states that recent experimental research by others has confirmed his clinical findings in regard to the features of the high blood-pressure preceding acute pulmonary edema from functional insufficiency of the left ventricle. The discovery of a high maximal and minimal blood-pressure should warn of possibly impending pulmonary edema and should be the signal for reducing the minimal arterial tension, the peripheral resistance, and for this, he says, there is only one means; that is, regulation of the diet. All causes for exogenous intoxication should be avoided, as also any unusual amount of salt; the diet should be chiefly milk and vegetables, with as little salt as possible, supplemented by a carefully supervised course of diuretic mineral waters. The heart is then equal to its task and no tonics are required. After an attack, the heart having shown that it has become insufficient, the above measures should be supplemented by tonics to strengthen the heart, especially digitalis. During an attack of acute pulmonary edema bloodletting certainly gives great relief. Morphin given in the hope of combating the dyspnea generally proves disastrous, as it adds the toxic action of the drug to the other burdens under which the kidney is already laboring.

42. **Subacute Hemorrhagic Pancreatitis.**—Leriche and Arnaud report a third case of hemorrhagic pancreatitis in which they have operated. The patient was a man of 48 who had been suffering for two months with recurring pains in the left epigastrium, growing constantly more intense, and radiating backward. A tumor could be palpated under the false ribs while the patient was very anemic and weak. Cancer in the colon was assumed, but the laparotomy revealed merely traces of a recent hemorrhagic pancreatitis with an encysted hematocele which had recently suppurated. The hemorrhagic tendency was revived by the operation, and the patient succumbed

the next day to the constant oozing of blood from the wound. The case teaches that when a hemorrhagic pancreatitis has reached the stage in question the operation should be deferred until healing is a little more advanced unless intervention is urgent. The cachexia and the tumor were the chief symptoms in this case, and they diverted attention from the differentially even more important symptom of the local pains.

45. **Albumin Reaction in the Sputum.**—Raymond's experience confirms the appearance of albumin in the sputum whenever there is any lesion of the parenchyma of the lung, an alveolitis. It is a constant accompaniment of serofibrinous pleurisy and acute congestions of lungs and pleura. Cautious interpretation of positive findings throws light on the lesions involved, as he shows by a dozen clinical cases. In one of the cases the positive albumin reaction, in connection with persisting temperature and the history of the case, seemed to indicate that an old and healed tuberculous lung process had flared up anew under the influence of an attack of measles. In other cases the acute character of the febrile lung affection giving the albumin reaction, the connection with a simple bronchitis, the albuminuria and absence of tubercle bacilli in the sputum—all indicated that the trouble was a comparatively transient pulmonary affection, possibly the work of the pneumococcus. The persistence of the albumin reaction for some time after recovery reveals the lesion of the lung parenchyma, which is the true substratum of the affection; the vascular congestion is not the main feature of the cases, but rather the active exudation into the alveoli, as well as into and under the pleura. The alveolitis is responsible for the main physical signs observed. In one of the cases reported the negative albumin reaction excluded tuberculosis, and showed that the trouble was a simple chronic bronchitis and emphysema in an old case of healed pulmonary tuberculosis.

54 *Fracture of the Spine in the Neck Without Cord Symptoms. (Des fractures du rachis cervical sans symptomes médullaires.) J. Boeckel and A. Boeckel. Commenced in No. 6.

50. **Tuberculous Hip-Joint Disease.**—Vincent adds a number of points and details to complete Coudray's article on this subject published in the *Revue* last April. Vincent advocates resection for a certain group of cases in young children, but not for adults or older children. He applies resection only after failure of all conservative measures, but insists that when it is done in time it will save many a child who would inevitably succumb if left to Nature's efforts alone or even aided by the whole train of modifying injections, immobilization, extension, traction, fresh air, sea bathing and all other hygienic measures.

51. **Osteomyelitis of the Sacrum.**—Gaudier and Bertein have found twenty-seven cases of osteomyelitis of the sacrum in the literature, including nine reported by French authors. The prognosis is graver than for osteomyelitis elsewhere in the spine, the signs of general infection are more pronounced. They explain this by the anatomic arrangement of the parts owing to which the infectious focus is walled in deep and may not monifest itself for some time. The germs thus shut up in a closed cavity have their virulence exalted and induce general infection with serious phenomena, sometimes even before the focus has been brought to the patient's attention. Operative treatment is indicated at the earliest possible moment to ward off severe general infection or attenuate it. They give the details of the total twenty-seven cases; operative measures, even the most extensive, failed to save the patient except in seven instances, including Hunt's and Young's cases.

53. **Instruments for Perineal Prostatectomy.**—Martini uses a kind of cat's paw instrument to draw up the whole prostate, the three claws folding together as the instrument is introduced. Guided and sheltered by this instrument, another is introduced with a scoop at the tip made of three triangular sharp blades. This resects the prostate tissue, while it is impossible, he says, for it to cut too far or injure the bladder wall. The article is illustrated.

54. **Fracture of the Spine in the Neck Without Spinal Cord Symptoms.**—Bœckel declares that the prognosis of fracture of the cervical spine has been shown up in an entirely new light by the Roentgen rays which have revealed that even extensive fractures may exist and heal without any spinal cord disturbances, and that fractures of the cervical spine, atlas and axis are much more common than hitherto supposed, and explain many hitherto puzzling conditions, the latent fracture having been taken for a sprain, contusion, rheumatism or neurosis or the patient accused of simulation. An early diagnosis is of the greatest importance to ward off mischief later; when trouble does occur it is always extremely serious, if not fatal. Fifty-seven cases are described from the literature or previously unpublished records, and the various differentiating symptoms and best technics for treatment in the different cases are reviewed. The mortality was 34.3 per cent. in the total number and only 22.2 per cent. when the fracture involved the third to the seventh cervical vertebræ. Fracture of the vertebræ above these is much more serious, the mortality having been 45.1 per cent. in his series. At the same time all the seventeen patients have recovered of the former class and the fourteen patients in the latter class, since roentography has been introduced. These figures show that the prognosis of fracture of the spine without injury of the cord has been transformed since it has been possible to recognize it early and apply proper treatment to insure consolidation in a good position, restoring the spine to its normal length and preventing the vertebra above from pressing on the fractured vertebra, while at the same time preventing tardy compression of the spinal cord later from overexuberant callus or traumatic spondylitis. The physician should superintend the transportation of the patient so that the fractured bones may not become displaced. Chipault advises laying a large plank beside the patient after the accident, covering it with a folded sheet, with a crosspiece arranged at the level of the neck; four persons are to lift the patient on the plank while the physician lifts the head and neck with both hands. He has known of persons without spinal cord symptoms after an accident of the kind to become paralyzed or succumb as they were lifted to carry them away. A radiograph should be taken before the patient is removed from the plank to his bed with similar precautions. The fracture should then be gradually reduced and immobilized or extension may be necessary, eventually kept up for a year or longer. Boeckel has compiled nearly a hundred cases of fracture of the cervical spine which healed promptly under these measures. Tardy accidents in other cases have sometimes required rupture of the callus, laminectomy or the figure-eight wire ligature. Defective healing of the fracture causing trouble in some cases was cured by renewed reduction and extension.

August 30, No. 35, pp. 409-420

56 *The Unappreciated Rôle of Acute Gastritis in Infectious Diseases. L. Cheinisse.

55. **Vertigo of Intestinal Origin.**—Loeper demonstrates how the apparatus of equilibration is liable to be affected by toxins generated in the intestines, by irritation of the nervous elements directly or by vasomotor fluctuations in the tension in the semicircular canals. These variations in tension may be independent of the general circulation, and to determine this the general arterial tension should be investigated, as this, in connection with hypertoxicity of the urine and other phenomena of a toxic order, distinguishes toxic from reflex vertigo. Treatment should be addressed to the bowels, supplemented by amyl nitrite in case the arterial tension is very high or spartein, strychnin, ether, bromids or valerian in case it is low. All irritating foods should be avoided, as also large amounts of fluids which suddenly increase the mass of

the blood. It is important not to depress the patients by a too exclusive or debilitating diet. Many such patients are already excessively nervous and all become so if the vertigo persists, which should be borne in mind in treatment with means to reduce the excitability of the neuromuscular system.

56. **The Unappreciated Rôle of Acute Gastritis in Infectious Diseases.**—Cheinisse does not accept Jerusalem's view that the relics of interstitial gastritis with proliferation of connective tissue which he has discovered at necropsies as such a constant phenomenon in acute infectious diseases, are merely a functional disturbance from the general infection. Cheinisse has encountered several cases of erysipelas and mumps in which the gastric symptoms dominated the clinical picture and could be explained only by assuming a localization of the specific infectious process, the erysipelas or the mumps, in the stomach. The prognosis differs naturally if the acute stomach trouble is a localization of erysipelas or mumps, especially when it is borne in mind that phlegmonous gastritis is not such a rare occurrence as formerly supposed. Cheinisse had a case of the kind in 1909, the phlegmonous gastritis developing in the course of an apparently mild erysipelas. The considerations presented suggest the importance of leaving the stomach in repose during the "gastric phase" of any acute infectious disease.

58. **Reinfection with Tuberculosis.**—Freymuth is chief of the great Belzig sanatorium and he has been reviewing the files of the institution to learn the chances for reinfection at such sanatoriums. He examined the records of 1,400 adults and 328 children, inmates of the sanatorium in 1908 to 1910. He found only thirty cases among the adults in which tubercle bacilli were found in the sputum after they had been in the sanatorium some time, while none were discoverable when they entered, that is, only in 2 per cent., while only two of the children, that is, 1 per cent., came into this category. The interval was only from three to eight days which excludes the possibility of reinfection. The findings related confirm, he thinks, that there is not the slightest necessity for separating the patients with closed from those with open tuberculous lesions. The healthy are exposed to droplet infection, but he knows of no case on record in which a healthy person became infected with tuberculosis in a sanatorium. This may be due to the fact that the supposed healthy are already infected with tuberculosis and consequently immune, or to the fact that the residence in a sanatorium for lung disease induces immunization in time. The question still open to discussion is whether the life in common of patients with open and closed pulmonary tuberculosis may not lead to transmission of mixed infection, and hence that patients with demonstrated mixed infection should be isolated.

61. **Interruption of Pregnancy in Tuberculous Women.**—Schottelius calls attention to the strange fact that older observers used to ascribe a beneficial influence to a pregnancy in the course of pulmonary tuberculosis, while in recent years the tendency has been to attribute a very harmful influence to it. He regards abortion as indicated whenever pulmonary tuberculosis is diagnosed beyond question as his experience shows that in at least 75 per cent. of all the cases the lung affection rapidly progresses during the pregnancy and puerperium. The written consent of the patient and her husband and of a consulting internist are necessary—the responsibility lies with the family physician or the consulted lung specialist. Once decided, the pregnancy should be terminated as soon as possible and be supplemented by tubal sterilization if the woman has already borne more than one child. The more pressing indication for hysterectomy in these cases is excessive uterine hemorrhage. The disturbances from castration should turn the scale in favor of leaving the ovaries. The sterilization induced by exposure to the Roentgen rays destroys the ovaries and thus is equivalent to panhysterectomy, but it has the advantage over this of being a bloodless procedure, not requiring general anesthesia.

62. **Subcutaneous Tuberculin Test After Diagnostic Inoculation of Animals.**—Jacoby and Meyer advocate a subcutaneous injection of 0.5 c.c. of tuberculin two weeks after the animal has been inoculated with the suspected sputum, as a means to simplify and hasten the findings. They report twenty-seven series of experiments with a total of 221 guinea-pigs including forty-three control animals. Fully 88 per cent. of the animals given the test, in from eleven to fourteen days presented a marked reaction; the results were conflicting or negative when the sputum had been previously treated with alkaline solution of sodium hypochlorite (antiformin). The animals giving a positive reaction either died or showed a marked drop in temperature of at least 5.4 F. The anatomic findings were positive in every case giving a specific reaction. They advise using three guinea-pigs, not over 250 gm. in weight each, injecting on the eleventh, the sixteenth and twenty-first days, making a subcutaneous injection of 0.5 c.c. tuberculin. It is thus possible to clinch the diagnosis within two weeks.

72 *Differential Atmospheric Pressure in Lungs by Impeding Expiration. (Einfaches Ueberdruckverfahren.) E. Aron.

67. **Treatment of Aphonia.**—Seifert discusses the five groups in which spastic dysphonia may be classified, the hysteric, the reflex, the professional neuroses, those accompanying cerebrospinal affections, and the group in which no causal factor can be discovered. He has obtained exceptionally fine results in this latter class by a method which he describes in detail, aiming to exclude causal spasms in the muscles of the neck, abdomen and diaphragm, while training the patient to speak, on the same principles as in the treatment of stuttering. He accomplished this by having the patient lie across a sofa, the back of his neck supported on the thigh of a third person sitting near the sofa while the patient's head drooped a little, the feet supported on a stool. In this position the patient was trained to breathe deep and regularly and relax all the muscles. After two or three days he had learned to do this and then he was told to whisper "ah" and "ay" and then gradually increase the sound while the physician compressed the abdominal walls after each deep inspiration. The patient was taught to speak with as deep a voice as possible. After two weeks of these exercises he was able to do them sitting up, pressing on the epigastrium to exclude the contractions of the abdominal musculature and diaphragm. By the end of the month the patient was quite cured. He was a man of 36 and the aphonia had developed over two years before and was complete, not obtaining any relief until this course of exercises. A letter from him over a year later confirms the permanency of the cure, and his recovery is evidenced in an official communication from the mayor of his home town, a city with 16,000 inhabitants, expressing the universal gratitude for his cure.

70. **Stretching the Pylorus with Benign Stenosis.**—Einhorn's work was described in The Journal, May 27, 1911, p. 1607.

72. **Simplified Differential Pressure Procedure.**—Aron reports experimental research which demonstrates that a device impeding expiration keeps the lungs permanently inflated, even during expiration, so that the thorax can be opened without its collapsing. It is possible that this principle may be applied in operations on the human chest. His technic requires a preliminary tracheotomy.

73. **Arsenic the Digitalis of the Metabolism.**—Cloetta thus calls arsenic in his article reporting experimental research on its action. He found that animals fed with arsenic developed much better in every respect than the controls from the same litter. That this better physical development includes the vital tissues, and is not merely increased accumulation of fat, is shown by the fact that the total tissues of the animals ground into a homogeneous mass, from which water and fat were extracted, showed a larger proportion of nitrogen in the arsenic animals than in the controls. He accepts this as evidence that the arsenic actually promotes the metabolism as digitalis promotes the action of the heart—laboratory research thus lumbering along to explain the facts observed by empiric observation generations ago. He fed dogs with arsenic over long periods, one of the dogs, a fox-terrier, he thinks, must be accorded the record for eating arsenic, as he took 0.5 gm. of arsenic daily for two months and then 2.6 gm. a day without harm, the arsenic feeding being kept up for over two years. Cloetta's further research, however, swept away the idea that the animal had become habituated to the drug, as it was proved that he merely had ceased to absorb it. The lining of the alimentary canal had evidently become modified in such a way that it ceased to absorb the arsenic. This is probably the explanation for the resistance to arsenic acquired by trypanosomes in time and suggests the importance of supplementing salvarsan or other preparations of arsenic with mercury to which the spirochetes do not acquire resistance so soon. For the same reason he hails with approval the efforts to use preparations of antimony against the trypanosomes. There does not seem to be any habituation to antimony, and the proportion absorbed does not progressively decline as is the case with arsenic. He adds that Rowntree and Abel's recent work in this line in this country confirms the results obtained in his researches on dogs in regard to the trypanosomes becoming proof against arsenic and antimony.

74. **Glycerin Dressings for Infected Wounds.**—Rusca is seeking to revive glycerin as a dressing for wounds. Its water-attracting power serves to reduce the congestion in the region while it keeps the wound clean by taking up the secretions and softening the necrotic tissue and crusts so that they can be readily removed, thus depriving the germs present of their favorite nests. Glycerin has also a slight sterilizing action which might be enhanced by addition of some disinfectant. There cannot be the slightest danger from the use of glycerin; he continues, as even taken internally in large doses there does not seem to be any toxic action. He saturates a compress with official glycerin and applies it to the lesion, covering with an air-tight cover, and changes the dressings twice a day. He has obtained excellent results with this technic in 100 cases of various local infectious processes, the lesions soon clearing up and healthy granulation following, except the tuberculous lesions; these do not seem to be influenced. The glycerin dressings are free from the coagulating action on albumin which is one of the disadvantages of alcohol dressings.

78. **Subcutaneous Drainage of Ascites.**—Tavel uses a glass spool with broad ends, the hole through the center 1 cm. in diameter. One end of the spool is worked through into the peritoneal cavity and an ample hole to hold the other end of the spool is made for it in the subcutaneous tissue. Not even local anesthesia is required for the insignificant operation of introducing the spool; the only point is to manage so that omentum will not get into the lumen and obstruct it. He has used the spool in five cases which he reports in detail, the outcome being excellent in all, the ascites draining effectually and harmlessly into the subcutaneous tissue.

83. **Chronic Salvarsan Treatment of Syphilis.**—Kromayer asserts that the experience acquired with other drugs in the treatment of syphilis teaches that it is impossible to eradicate the disease at one stroke, no matter how large the dose of mercury or other drug. Success is possible only with long continued small doses, and the same is evidently true of salvarsan. He has been giving it on this priniciple for nearly a year, making an intravenous injection of about 0.2 gm. of salvarsan three times a week, up to a total of 3.6 gm. Of 365 patients thus treated he has recently had 136 reexamined and the findings confirm his statements that this is by far the best method of treating syphilis at our disposal. There was no neurorecurrence in any instance and no recurrence of symptoms in any case in which the total dosage had amounted to over 1.6 gm. of salvarsan. He is convinced that inadequate dosage of salvarsan as well as of mercury, exposes the patient to the danger of recurrences in a serious form more than if he had not been treated at all. It is his practice to give some mercury with the salvarsan, and the fact that the neurorecurrences subside under calomel he accepts as evidence that they cannot be due to intoxication from the salvarsan but are actually manifestations of the syphilis.

86. **Pericardiac Pseudocirrhosis.**—Fogarasi discusses the mechanism and development of polyserositis, especially that form which Pick has described as pericardiac pseudocirrhosis. It may develop from polyserositis alone or from stasis resulting from mischief in the pericardium, the syndrome being practically identical, although the mechanism may thus be so widely different. To sustain these views he reports a case in which a boy of 17 was hit in the heart region; after five months pericarditis developed, keeping him in bed for six weeks. About three months later a tendency to edema of the ankles and anasarca became evident, the latter due to stasis of both mechanical and tricuspid origin, the liver becoming enlarged at the same time.

88. **Wassermann Reaction Not Pathognomonic of Lead Poisoning.**—Perussia states that he found the reaction constantly negative in thirty-five non-syphilitic patients with various manifestations of lead poisoning and three others who had been infected with syphilis in previous years but had received vigorous treatment. His findings conflict with those of Dreyer, who obtained a positive reaction in sixteen similar cases among sixty patients examined, and Schnitter's, who found the reaction positive in four of sixteen cases.

89. **Surgery of the Vessels.**—Heymann reports the complete cure of angiospastic gangrene in a man of 47, a teacher, by diverting the arterial blood into one of the veins in the forearm. He gives an illustrated description of the technic; the benefit realized at once has persisted unmodified during the ten months to date of writing.

90. **Pelvic Tuberculosis in Women.**—Neu has been able to reexamine seventy-seven women who had been under treatment for genital or peritoneal tuberculosis at the Heidelberg clinic between 1902 and November, 1910. Of the fifty-five given operative treatment, 75 per cent. were living and 52 per cent. of the twenty-one treated by conservative measures. On account of the uncertainty of the diagnosis and prognosis of tuberculous processes in the peritoneum and genital organs, operative treatment is indicated, he thinks, if there are no advanced tuberculous lesions elsewhere, particularly in the lungs. The operation should be as radical as possible, including in case the genital organs are involved removal of the uterus, both tubes and the ovary affected. In the inoperable cases, the conservative measures then indicated should include Roentgen therapy. A course of sanatorium treatment before or after operative treatment is extremely desirable. Neu protests against exploratory puncture, advocating rather an exploratory incision. He warns further against the dangers of diagnostic tuberculin tests. The reaction is liable to be far from harmless; he has witnessed cases in which the diagnostic injection of tuberculin seemed to start the process to a progressive course or it had a most unfavorable influence on a tuberculous process elsewhere, especially in the lungs, and depressed very much the general health. He inquires whether others have had similar experiences. He regards exploratory curetting likewise as liable to prove dangerous.

91. **Gastric Tetany.**—Bircher writes from Switzerland, where tetany is comparatively rare, to report several cases of gastric tetany, some with a fatal outcome, and a case of tetany in a soldier after overexertion. The features in the latter case suggested a combination of idiopathic with gastric tetany. In another case the tetany developed in the course of recurring gastro-intestinal disturbances in a man of 30, a hard drinker. After five days of ileus, tonic spasms developed in the neck and muscles of the jaw and cramps in the legs. Necropsy showed the stomach enormously dilated and the jejunum kinked 1 cm. below the pylorus. In three other cases the spasms came on two or six days after appendectomy in children between 5 and 17 and proved fatal in a few hours. A toxic action from the peritonitic effusion seems to have been the probable cause of the tetany in these cases, and he thinks that this may occur more often than supposed and that surgeons should bear its possibility in mind. In another case a woman of 39 of a neuropathic family had anterior gastro-enterostomy done for stenosis of the pylorus from ulcer. The stomach was found much dilated, but there was no tendency to tetany. The pylorus was so closely adherent to the liver that it could not be detached. At the ninth day of convalescence tetany developed and soon proved fatal. The gastro-enterostomy was found doing its work and Bircher is inclined to attribute the tetany in this case to lack of water in a predisposed subject—the rectal injection of water had not sufficed to quench the thirst. He knows of no similar case on record in which tetany was brought on by an operation on the stomach. In another case a similar operation cured tetany in a farm hand, the extreme irritability of the musculature in this case surpassing anything of the kind he has ever heard of. The man had had a goiter removed twenty years before.

92. **Two Simultaneous Forms of Abdominal Disease.**—Walzberg reports three puzzling cases in which an intestinal ulcer and appendicitis were associated or umbilical hernia and ileus, the latter explained by a cancer in the transverse colon, or there was an umbilical hernia plus hernia in the median line and thrombosis of the mesenteric vessels. In the last mentioned case the thrombosis was in such an incipient stage that it was not recognized and the abdomen was sutured after the herniotomy. Walzberg gives the details of the cases on the principle that one learns most from one's mistakes. The symptoms had been ascribed to the partial incarceration of the bowel in the hernia openings and to a cord-like adhesion connecting the omentum with one hernial sac. The root of the mesentery was seen studded with fan-like extravasations and some of the vessels were gorged with blood. Nothing macroscopic could be detected on the connected loops of intestines and the abdomen was sutured. The third day symptoms developed, showing that there must have been incipient embolism at the time of the operation.

106. **Influenza of the Brain.**—Stepp says that not enough attention has been paid to the cerebral disturbances liable to be directly induced by influenza localizing in the brain. In his three cases the patients were free from cardiovascular trouble and all were in the forties. The disturbances developed gradually at first, paralysis of the cheek, then hemiplegia and after a few days the other side was affected. The trouble is probably a disturbance in the smallest capillaries of the brain, inducing diapedesis. Complete recovery may follow or the extravasations may become confluent as after ordinary apoplexy. This recalls the fact that in most cases influenza begins with intense headache. It also suggests that persons with arteriosclerosis are exposed to peculiar danger during epidemics of influenza, and that under the influence of the infection ordinary apoplexy may occur with unusual frequency.

110. **End-Results of Operative Treatment of Non-Pyloric Gastric Ulcer.**—Zweig has records of twelve cases in his practice in which a gastro-enterostomy was done for a gastric ulcer, not located near the pylorus. The outcome was good in only five of the twelve cases; four deaths and three severe recurrences show that gastro-enterostomy under these conditions is a dangerous operation and benefits only in the rarest cases. These experiences, he adds, stand in marked contrast to the rosy reports from the surgical clinics. In conclusion he reports a case which shows that the success of operative treatment is not always attributable to the operation. A man with recurring gastric hemorrhage was so debilitated that jejunostomy was contemplated but the patient refused

an operation and was freed from all disturbances by a six-months' course of treatment in a sanatorium. He has had no trouble since, showing that even in apparently desperate cases of gastric hemorrhage the hemorrhage may finally stop of itself without surgical aid.

112. **Puerperal Auto-Infection.**—Zangemeister declares that this term should be dropped in favor of "infection with endogenous germs." From this point of view the prophylaxis of puerperal infection is seen under a new aspect. It may be the result of (1) any spontaneous or artificial inoculation of these endogenous germs; (2) the production of fresh wounds, thus favoring the inoculation with the endogenous germs; (3) by importation of germs from without, and (4) by the inducing of fresh wounds, inoculating these germs. The obstetrician may thus be responsible for a puerperal infection in any of these four ways and prophylaxis should bear each of the four in mind. Among the dangers are interference with the escape of the discharges, stagnation of the lochia in the first days after delivery, or by palpation of the uterus or extra-uterine maneuvers the germ may be inoculated into already existing raw points. It is possible that germs introduced by the obstetrician's hand may not be inoculated into a wound at first, but erosions may occur later into which the germs may finally get, or the maneuvers may be with a germ-free hand or instrument, but the resulting wounds may become infected later by germs already present. These possibilities have been demonstrated again and again in his clinical experience and experiments on animals. His views in regard to infection from the germs already present should not lead to disregard of the dangers of infection from without, but they open our eyes to the hitherto unrecognized enemy from within and place new weapons in our hands to ward off this danger which we have heretofore run blindly into. His statistics in 220 cases show that the women had streptococcus infection quite as frequently when they had not been examined as when this had been done.

114. **Influence of Passive Exercises on the Circulation.**—Veiel and Zahn report study of the conditions in the circulation, during and after application of Büdingen's apparatus for "hill climbing in bed" (mentioned in The Journal, April 29, 1911, page 1302). The findings indicate that these passive exercises have the same favorable effect on the circulation as vigorous active exercise only in a lesser degree.

115. **Stasis Hemorrhage in the Skin.**—Strauch has been testing on 180 patients and 160 healthy persons the effect of application of a constricting band to the arm, which Rumpel and Leede have advocated as a test for the presence of scarlet fever by the resulting minute hemorrhages in the skin at the bend of the elbow which they regard as pathognomonic for scarlet fever. Strauch, however, found it very frequent in all kinds of diseases and in health; in 68 per cent. of nineteen cases of acute rheumatism, in 37 per cent. of eight cases of diphtheria, in 62 per cent. of typhoid, malaria, etc., and in nearly half of the healthy persons tested.

117. **The Syphilis Spirochete.**—Hoffmann cooperated with Schaudinn in the discovery of the *Spirochæta pallida* and he here presents evidence to show that this is the proper scientific name for it.

121. **Psychic Influence on the Heart Action.**—Lederer and Stolte have found that the heart sounds can be modified in children with unstable hearts after scarlet fever by merely threatening or frightening the children. The mere sight of instruments was enough to modify the heart sounds under the stethoscope and they believe that their experiences in this line sustain the assumption of the possibility of sudden arrest of the heart action under emotional stress.

124. **Vomiting of Pregnancy.**—Foerster suggests on the basis of clinical experience that changing the position of the gravid uterus in some slight measure might act on the uncontrollable vomiting of pregnancy, either at the time or in prophylaxis.

129. **Hemorrhagic Encephalitis Following Injection of Salvarsan.**—Fischer's patient was a physician only 40 years old, who had recently contracted syphilis in his professional work, the primary sore being in the nose. He was given an intravenous injection of 0.4 gm. salvarsan, followed by thirty mercurial inunctions. After an interval of five days, thus forty days after the first injection of salvarsan, the same amount was injected again and two and a half days afterward symptoms of severe acute hemorrhagic encephalitis developed, which was rapidly fatal. Fischer cites a case recently reported by Plötzl and Schüller in which a rapidly fatal hemorrhagic encephalitis developed in a woman in an early stage of syphilis under mercurial treatment. These and other facts observed lead Fischer to ascribe the encephalitis in his and similar cases to a process of anaphylaxis, but the further fact that this is observed only in syphilis, suggests that the disease is liable to entail certain molecular changes in the brain substance, possibly some modification in the colloids of the brain, which may also be at the base of the parasyphilitic affections. The danger of encephalitis seems to be greater with a second injection of the drug. Fischer adds that the resemblance to anaphylactic phenomena suggests the possibility of therapeutic influencing of the severe cases of encephalitis under these conditions by measures which have proved useful in combating anaphylactic phenomena in experiments on animals, especially the narcotic drugs.

130. **A Fatality After Salvarsan.**—In Kannengiesser's case epileptiform convulsions followed an intravenous injection of salvarsan four months after a subcutaneous injection of the same drug. The patient was a robust butcher of 29. After the convulsions consciousness did not return and the clonic cramps continued with delirium, until death occurred from aspiration pneumonia. The threatening symptoms developed three hours after the injection of salvarsan, but necropsy failed to disclose any satisfactory explanation of the case.

131. **Acute Hemorrhagic Encephalitis After Salvarsan.**—Almkvist reports his one fatality in the 184 cases in which he has given salvarsan. This patient was a man of 32, infected with syphilis in 1905, the primary manifestations soon yielding to mercurial treatment. On recurrence of mild local symptoms in 1910, another course of mercurial treatment was given and in February, 1911, he was given an intravenous injection of 0.6 gm. salvarsan. Symptoms of gastric and brain disturbance became evident the second and third days and at necropsy, six days after the salvarsan injection, the brain showed traces of acute hemorrhagic encephalitis, the blood escaping by diapedesis as in infectious processes. The brain may have been peculiarly sensitive in this patient as he had had much business worry and sought recreation and relief from insomnia in distractions of varied kinds.

137. **Technic for Intravenous Injections.**—Knauer calls attention to the vibratory thrill perceived by the fingers placed on the vein above the point where the injection is being made. If this vibratory thrill from the instreaming fluid is not perceived, the fluid is not entering the vein properly.

140 Rare Defects in Speech. (Einige seltene Sprachfehler und partielle Rhinolalia aperta.) F. Neumann.
141 The Franzensbad Mineral Mud. (Das Franzensbader Eisen-Mineralmoor.) H. Klonka.

139. **Weakness of the Heart After Purging.**—Jaworski calls attention to the aggravation of heart disturbances or their first development in certain cases when attempts are made to relieve constipation medicinally. He calls the condition diarrheic hypodynamia of the heart, and reports five typical cases. They are observed comparatively often in private practice. Besides the loss of fluids in the diarrheic stools, the purge or laxative induces hyperemia and congestion in the abdominal organs and the blood is thus drained away from the skin, muscles and brain and the heart does not have enough blood to pump with. If the heart is in good condition there is no trouble, but if the myocardium is injured from any cause, symptoms of "reflex shock" develop; the external temperature declines; the skin is cool and pale, with more or less general weakness, dizziness, small soft pulse and apex beat, and slight heart sounds or arrhythmia. Treatment should aim to equalize the circulation, with hot-water bottles, nux vomica to contract the intestinal vessels, and strong coffee and tea to dilate the vessels in the brain and periphery. The movements of the intestines should be checked by some opium preparation and transudation into the bowels by some styptic. Persons inclined to weakness of the heart under these circumstances should be warned in particular against a systematic course of the widely advertised purgatives; Jaworski knows of cases in which this led to progressive fatal cardiac insufficiency. The elderly are in greater danger than the young on account of the tendency to arteriosclerosis. With advancing years the inhibiting and regulating influences grow weaker, so that the heart has to depend more and more exclusively on its own myo-automatism. The slightest injury of the myocardium then entails irregular action. He warns further that the same may be said of conditions in the acute infectious diseases in which the heart is suffering from the action of toxins; extreme caution is necessary in ordering purgatives and laxatives in order not to weaken the heart still further. These patients may ask to be purged to get rid of annoying tympanites, but he has often noticed that the face was pinched with other signs of collapse after the drug had operated. It is possible, he adds, that a purge might serve as a test for the diagnosis of latent cardiac insufficiency.

146 *Camphorated Oil in Treatment of Peritonitis. (Anwendung des 1%igen Kampferöls bei Peritonitis und die adhäsionshemmende Wirkung desselben.) O. Hoehne.

143. **Operative Treatment of Hydrocephalus.**—Marimon aimed to drain the lateral ventricle permanently into the parotid gland which he considers particularly adapted for rapidly taking up the fluid thus emptied into it. He gives an illustrated description of the procedure as applied to an eight-months infant with extreme hydrocephalus, the head measuring 63 cm. in circumference, the eyeballs forced down so that the white sclera alone was visible. The operation induced a marked improvement after its application on one side; vision became normal and the head much reduced by the fifth week after the operation, but then the child succumbed to an intercurrent enteritis. He pierced into the ventricle with a long curved needle forcing it out through the skin below and drawing back the silk drain. The silk was then carried down through the subcutaneous cellular tissue into the middle of the parotid, which required several insertions of the needle. The technic is similar to that of Handley's method of providing new lymph routes in elephantiasis of the limb. The technic is simple but the oozing of cerebrospinal fluid through the needle holes retarded healing. Marimon had intended to apply the same operation on the other side.

145. **Treatment of Exstrophy of the Bladder.**—Chlumsky avoids the tendency to incontinence of the new bladder-wall, when it is formed by transplantation, by leaving to Nature the task of closing the bladder-wall. This insures durable closure. He separates the skin from the mucosa of the bladder and allows it to retract and waits patiently for the healing over of the wound thus made. There thus forms on the operated point a layer of epithelium, free from hairs, whose surface is further enlarged by the fact that the bladder being cut around is pressed forward like an umbilical hernia by the abdominal pressure. He has operated in this way in two cases and the bladder became closed in one and was on the way to closure in the other when the infant acquired bronchitis and the wound tore apart. Chlumsky states that the works on operative treatment of exstrophy of the bladder now number over 179, but the end-results of treatment to date by the usual methods still leave much to be desired. So he thinks there is a future for his simple technic for plastic closing of the bladder which in his successful case resulted in the production in time of a large bladder corresponding entirely to a normal one.

146-7. **Prophylaxis of Peritonitis.**—Hoehne refers to the injection of camphorated oil before a laparotomy to induce an aseptic irritation of the peritoneum, and reports remarkably favorable results in over 120 cases. He describes the technic in detail; no anesthetic is required as the blunt needle is inserted through a minute incision, and 30 to 50 c.c. of the 1 or 10 per cent. camphorated oil are injected from one to four days before the operation, in "ante-operative irritation treatment" of the peritoneum, and presents evidence to prove that the reaction thus induced may persist for two weeks or longer, even to seven weeks in one of his cases. According to experience to date, the exudation resulting from the irritation is gradually absorbed and never induces adhesions as long as it is aseptic.

149. **Protection of the Perineum.**—Brock noticed years ago that when the perineum tore during a forceps delivery the laceration corresponded to the blades of the forceps; the pressure from them had reduced the vitality of the tissues, so that they tore at these points. This fact suggested to him that even the pressure of the fingers, while striving to prevent injury during expulsion, may be the very factor which produces the tear. He now teaches always that the perineum should be given time to stretch spontaneously, and the head should be pushed gently back until the maternal soft parts have stretched gradually to their utmost. The accoucheur's hands should not touch the perineum but merely hold back the head, the fingers not curving but spread more nearly flat until the wrist touches the back of the child's head; then, by slightly lifting the chin, the lowest portion of the face can be released. He calls this the passive or expectant method of protecting the perineum, and remarks that while it is far from being ideal, yet it avoids the dangers of the usual methods of pressure on the perineum from without.

151. **Pernicious Anemia in Pregnancy.**—Bauereisen reports two cases of pernicious anemia in pregnant women in which he cured the patients by daily subcutaneous or intramuscular injections of 5 or 10 c.c. of whole blood, seven injections being given in one and five in the other case. He commends this method for its simplicity and advises its wide adoption in general practice. The one yielding the blood sits near the patient; as soon as the blood is taken from a vein in the arm it is injected into the patient when still warm and the spot lightly massaged. The effect seems to be the same as when large amounts of defibrinated blood are used.

154. **Diagnosis of Extra-Uterine Pregnancy.**—Scipiades refers to a case of extra-uterine pregnancy in the broad ligament which had been carried to term. The condition was correctly diagnosed by the asymmetrical location of the tumor and its extension deep into the pelvis, while a cord-like structure could be palpated between the wall of the uterus and the tumor, and the surface of the tumor was smooth and sharply outlined.

157. **Syphilis and Scarlet Fever.**—Silvestri has been impressed with the way in which a pre-existing syphilis modifies certain other diseases and affords a favorable soil for the development of tuberculosis, which runs a grave course as a rule in syphilitics. In three recent cases of syphilis in his practice intercurrent typhoid had a particularly rapid and malignant course as also pneumonia and erysipelas in other syphilitics. On the other hand, the syphilis has been favorably modified by an intercurrent scarlet fever in three of his cases, which he reports in detail. In the first a child with severe manifestations of inherited syphilis began to thrive and has been in comparative health since after an attack of scarlet fever at the age of 4; the same was also observed in another syphilitic child. In his third case a man of 45 had long been suffering from severe manifestations in the third phase of syphilis, including disturbances suggesting gastric ulcer. An intercurrent scarlet fever transformed conditions so that after recovery from the latter there were no further disturbances from the syphilis, even the Wassermann reaction having become negative. The intercurrent infection seems to paralyze if it does not destroy the still existent spirochetes.

165. **Reflex Phenomena from Gynecologic Lesions.**—Bossi declares that no woman should be committed to an insane asylum until after thorough examination by a gynecologist, as frequently the mental disturbances are merely reflex phenomena from some curable affection of the genital organs. He reports three typical cases which sustain this view. The chronic tendency to irritability and melancholia or a recurring tendency to mania permanently subsided after operative and other measures to cure inflammation in the uterus or cervix or both, with or without rigidity of the cervix, and, in a fourth case, extreme anteflexion of the uterus with a tendency to atrophy.

166. **Brace for Fracture of the Clavicle.**—Zatti uses a rectangular sheet of metal, about 30 cm. long by 12 wide, bending it up to form a ridge in the center to fit over the spine. The plate is held in place across the back by a starched bandage wound in figure 8 folds seven times around the shoulders and across the back, as he shows in four illustrations. The front of the chest is left free and respiration is promoted instead of hindered, while the fractured bone is effectually immobilized and the patient can rest easily in bed.

172. **Hydrogen Dioxid in Sterilization of the Infected Uterus.**—Grandoni remarks that it was with considerable hesitation that he first used a solution of hydrogen dioxid for irrigation of the infected puerperal uterus, fearing gas embolism from the nascent oxygen. But his experience in a number of serious cases in which this measure was about the last resort, gave unexpectedly favorable results and has con-

vinced him that these fears are practically groundless. The foam from the nascent oxygen does not seem to have force enough to penetrate into the tubes or open blood-vessels. He cites the details of seven cases emphasizing the prompt way in which the conditions in the infected uterus returned to approximately normal. In the cases in which the infectious process was restricted to the uterus, irrigation with the dioxid conquered it at once. Even when the condition was one of true puerperal septicemia, local irrigation with hydrogen dioxid effectually supplemented the intravenous injection of a solution of bichlorid of mercury, according to Baccelli's technic, when conditions were apparently desperate.

183. Dangers of Foreign Bodies in the Intestines.—In Razzaboni's case an elderly woman had had an easily reduced femoral hernia for thirty years, when it became suddenly irreducible and painful. Attempts at mild taxis proving ineffectual, herniotomy was done and with apparent success, but in a few hours fecal vomiting developed with other signs of abdominal mischief, soon fatal. Necropsy revealed the presence of two fishbones in the colon which they had perforated at both ends of the bones. He believes that the perforation was the result of his efforts at taxis or during the operation, and warns that the unsuspected presence of a foreign body may singularly complicate an operation for hernia. The case is still another argument against taxis of hernias.

188. Gastric Ulcers Simulating Cancer.—Schilling reports a case of this kind in a man of 55. On opening the stomach the diagnosis of cancer seemed positive and the stomach was resected, but the microscope showed that the very large tumor in the larger curvature, adherent to the transverse colon, was a fibrous connective-tissue growth. But at the same time a minute tumor was found near the pylorus which proved apparently to be a true solid cancer. The patient had cause to rejoice over the mistaken diagnosis as seldom or never has a cancer in the stomach been discovered and removed at such an early stage. Syphilis and tuberculosis are often the cause of supposed malignant disease of the stomach; Schilling operated a year ago on a woman of 30, making a gastroenterostomy on account of a gastric tumor which was undoubtedly of tuberculosis origin, as there was a similar tumor in the cecum and the appendix was found on removal to contain a local tuberculous process. The patient has been clinically cured by the operation. A stomach affected with fibrous induration may also simulate cancer and he adds the history of a case of the kind, the signs of stenosis of the pylorus in a woman of 60 finally compelling resection of the stomach, after which the woman rapidly regained strength and weight. After five years of health symptoms returned and a tumor was found at the point of the anastomosis, simulating cancer, but the microscope revealed merely fibrous tissue. The patient was again restored to health by a further resection, but there was suppuration later in the wound and a fistula into the transverse colon with adhesions, finally compelling a third operation by the end of the year. After an anastomosis excluding the site of the lesion in the transverse colon, the fistula soon healed and the patient has been in the best of health during the six years since.

189. Operative Treatment for Genital Prolapse in Sweden.—Westermark here brings down to date his previous communication on this subject in 1897, when he tabulated the details and outcome of operative treatment by various Swedish surgeons in 140 cases of severe prolapse of the vagina and 456 of the uterus. The figures since that date include 411 cases of prolapse of the vagina and 817 of the uterus. All this material is sifted and the end-results tabulated and compared with the various technics used. Westermark's preferred method of treating prolapse of the uterus by lateral colporrhapy (published in 1892) was applied in 255 cases of prolapse of the uterus; 173 of the patients have been reexamined recently. A recurrence of trouble was discovered in only twelve cases, that is, the operation was entirely successful in 93.1 per cent. The recurrence was generally in the form of a cystocele. The entire statistics compare favorably with those in other lands.

RESECTION OF THE POSTERIOR ROOTS OF THE SPINAL CORD

WITH THE REPORT OF ONE CASE AND CITATION OF OTHER CASES AS A BASIS OF INQUIRY INTO THE COURSE OF THE SENSORY PATHWAY *

WILLIAM A. JONES, M.D.
Professor of Mental and Nervous Diseases, Medical Department, University of Minnesota
MINNEAPOLIS

To provide a suitable introduction to my subject, the following case is outlined:

History.—Mr. X. was first seen by me Dec. 24, 1908. He was 50 years of age, married, and the father of four living, healthy children. His father, who had been previously rheumatic, died at 82 of old age. His mother died of syncope at 64. He has one brother who is healthy and well except that he is an asthmatic. There are no nervous or mental troubles, tuberculosis, or malaria in him or his family. He was never nervously ill.

In 1881, when 26 years old, he was circumcised, and he may have had syphilis at that time, but the history of it is uncertain, and there were no demonstrable evidences of lues at the time of his first examination, in 1907. His habits have always been temperate and his bodily functions normal.

In 1891, or sixteen years before his visit, twitching began in his right forearm on the radial side. Later there was a dull ache in the same region, followed by shooting pains, spreading through the arm, involving the right arm and shoulder, and extending into the dorsal side of the head of the radius, and later centering at two main points, the thenar eminence and the lower attachment of the deltoid about the superficial aspect of the musculospiral nerve. Not infrequently the right scapula was the seat of pain. The pain-seizures were paroxysmal, and grew in frequency and severity, and they were apparently more or less influenced and aggravated by changes in the barometer.

In 1903, his pains became so severe that his musculospiral nerve was stretched; but not even temporary relief followed this operation.

Examination.—He came to Minneapolis Dec. 24, 1907, and exhibited during his visit here marked evidences of paroxysms of pain. He clutched wildly at his thenar eminence and at a point below the deltoid and behind the shoulder. These paroxysms recurred every day at short intervals during the day, but were less noticeable when his attention was diverted. He had no anesthesia of the shoulder, arm, forearm, or hand, nor in any other part of his body. His pupils were small, almost pin-points. *The right pupil was smaller than the left, irregular* in outline, and reacted slightly to light. His vision was myopic. These two symptoms, shooting pains and pupillary changes, justified the diagnosis of high tabes, made by his physicians, Drs. Frank Fry and William Graves, of St. Louis, who had had him under observation for years. A celebrated Scottish neurologist had made a diagnosis of neuromata of the cervical spinal nerves.

The reflexes, deep and superficial, of the arms, trunk, and legs, were normal. The station and coordination were good, and he had no ataxia of the arms or legs.

The few symptoms that were present made the diagnosis difficult, other than that a central cord lesion was probable.

Operation.—As he had been thoroughly medicated by mercurials and iodids he was told that there was one course open *to him, namely, a sectioning of a trunk nerve in the neck*, or laminectomy and posterior root section. The former operation was chosen, and a large connecting trunk, presumably between the fifth and sixth cervical nerves, was sectioned in the neck Jan. 8, 1908. Relief from pain and spasm was immediate, and he was reasonably comfortable for a few months. Gradually the paroxysms of pain returned, and he came again for relief. *Jan. 23, 1909, he was operated on by Drs. H. W. Jones and* A. S. Hamilton. An unilateral laminectomy was performed on the right side by cutting through the laminæ and exposing the cord with the roots from the lower half of the cervical segments. The dura was incised and the spinal fluid allowed to escape slowly. The incision was enlarged and the sensory roots of the fifth, sixth and seventh cervical nerves were raised on a hook with great care so as to include all of the fibers. The roots were then grasped with compression-forceps and resected, cutting them where they emerged from the cord and as near their emergence from the dura as possible. It was thought that all of the strands were exsected. The dura was closed with catgut, and the skin was closed with subcuticular silkworm gut.

Greatly to our disappointment and to the astonishment of the patient, he waked from his anesthetic in pain and agony and without a clearly defined area of anesthesia. A map of the usual distribution of peripheral sensory nerves was used as a basis of comparison, but the patient failed to verify the outlines on the map. By careful investigation we thought we discovered a change in sensation, but in a few days the arm had regained its natural sensitiveness. If there was any change in sensation at any time following the operation it was so slight as to be considered unreliable. The patient recovered from the operation, and his cervical spine was in no way impaired, but the paroxysms of pain increased in frequency and severity. He returned home, and during the spring and summer he suffered great pain, and was forced to use opiates.

Second Operation.—He went to St. Mary's Hospital, at Rochester, Minn., and was operated on by Dr. C. H. Mayo, Aug. 11, 1909. The unilateral laminectomy was repeated, and the sensory roots of the fourth and eighth cervical nerves were exsected. Dr. Mayo thought at the time of this operation that there remained a few filaments from the fifth, sixth and seventh nerves, which had been previously removed. This seems hardly likely, as the operation was done with the greatest care. *At all events, a marked anesthesia* should have followed the root section. The relief from pain after Dr. Mayo's operation was marked within a few days. The arm lost its spasticity and became more or less useless; and the right leg dragged, probably due to a superficial injury or hemorrhage into the substance of the cord.

The patient writes me under date of June 2, 1911, as follows:

"*I am free to say that, although I was relieved from the* terrible condition I was in, I am in anything but a satisfactory condition at present. My walking is impaired and the right leg has never entirely regained its power or control, and I

---

* Chairman's Address before the Section on Nervous and Mental Diseases of the American Medical Association, at the Sixty-Second Annual Session, held at Los Angeles, June, 1911.

> tire very quickly. There is a lack of sensation in the toes of the right foot; but that does not inconvenience me to any considerable extent. There has been quite a loss of sensation in the right shoulder and arm, especially along what I should call the top of the arm to the thumb, forefinger, and second finger, but there is always a terrible tension in the arm, especially in the forefinger. At times it almost seems as if the filaments would be drawn from the finger. I cannot describe it otherwise. When a change of the atmospheric conditions is approaching I feel it very severely, the throbbing and twitching of the hand being especially acute. On the lower outside portion of the arm (in a line with the point of the elbow) the sensation is not nearly so acute. I cannot use the arm, except to shake hands or to carry a light weight, such as an umbrella, and I might say that I have to make my arm do that and watch it while it is being done. At the back of the collar bone, at the foot of the incision of the operation of 1908, I have a sensation as if a hot iron were being pushed in there, and my neck muscles become rigid. As a matter of fact, I do not think the nerves are any more dead in the arm than they were before the operation, but, as I have said before, I have received considerable relief from the last operation. Unfortunately, on account of my lack of strength I cannot take much exercise, so have increased in weight to an uncomfortable degree. Prior to 1908 I never weighed over 172 pounds and before the operation at Rochester, in August, 1909, I weighed 135 pounds. To-day I weigh 195, and my weakness makes it hard to carry this weight.
>
> "In closing, I wish to say that if anyone in a condition similar to mine should ask my opinion, I would strongly urge him to avoid the knife. This may seem ungrateful, but while I suffered terrible pain, I had the strength to carry and use my arm. . . .
>
> "One thing I overlooked; at night I sometimes never move from lying down to getting up, but when the time comes to rise it is hard to get turned around and get up. My nerves strain me, and I almost feel as if I should become disjointed. The same condition occurs on a smaller scale if I have been sitting for a half hour or so. I might also add that when the atmospheric condition changes, the weight of my arm increases as if I were carrying a heavy weight on my shoulder. This is as near as I can describe my condition at present."

This case is only one of many reported in this country and abroad, in which an operation has been employed for the relief of pain, spasticities, athetosis, post-hemiplegic contractures, spastic paraplegia, and gastric crises in tabes.

To Dr. C. L. Dana of New York belongs the credit for this operation, and the first of its kind in this country was done by Dr. Robert Abbe, Dec. 31, 1888. Mr. Bennett, a London surgeon, under the direction of Sir Victor Horsley, operated on a similar case seven days before Dr. Abbe's operation. These episodes led to much open discussion, and the claims for priority of operation have never been definitely settled, but it has been conceded by other writers that the principles of the operation were first enunciated by Dr. Dana.

Förster, a Breslau surgeon, in 1908, wrote a very exhaustive treatise on root-section operation from its theoretic, as well as its practical, aspects, and he emphasized its usefulness in spasticities and athetosis. He reported five patients operated on by Tietze, one of whom was a girl of 11 years with painful spasms and nearly complete paraplegia following a tuberculous spondylitis. The third and fifth lumbar and second sacral roots were divided on the left side, and the third lumbar and first sacral on the right side. The relief from spasm and pain was decided, and there was improvement in locomotion. No disturbance of sensation followed the operation.

Chipault and Demaulin, in 1895, in the *Gazette des hôpitaux*, have contributed cases and literature.

Dr. Morton Prince in *Brain*, spring, 1901, records the section of a posterior spinal-nerve root for the relief of pain in a case of neuritis of the brachial plexus, following a Colles' fracture of the left wrist, in which there was absolute paralysis of nearly the whole left arm and reaction of degeneration, atrophy, and pain in the thumb and forefinger. Evidently the roots of the fifth, sixth and seventh cervical fibers were most severely injured. However, of these three the fifth and sixth suffered the most. The man was operated on three times; first the radial nerve was stretched; later, two other operations on nerve trunks were done. Before the operations there was anesthesia over the deltoid distribution and over the little, the ring, and one-half of the middle finger. This may have been due to one of the operations or to an extension of the neuritis. A laminectomy was done which produced a cessation of pain in the fore-arm. Later, a Brown-Séquard's paralysis developed, and still later there was a partial return of sensibility. The fifth, sixth and seventh cervical spinal roots were divided, and an absolute loss of sensation for touch and pain followed, limited to the whole thumb with its ball, the back of the hand, and a strip along the radial aspect of the forearm and arm. The palmar surface of the forearm and middle fingers and the region generally given to the sixth root were not anesthetic.

Dr. George W. Jacoby[1] recorded cases of posterior nerve-root section which were more or less benefited, and pointed out the dangers of a Brown-Séquard paralysis.

Abbe[2] records a case of intractable brachial neuralgia in which nerve-stretching and amputation had been done by another surgeon, and in which Dr. Abbe finally made an intradural division of the posterior roots of the sixth, seventh and eighth cervical nerves with improvement. During this operation an electrode was applied to the sixth nerve root, which caused contraction of the supraspinati and infraspinati, brachialis, latissimus dorsi, pectoralis major, teres, and deltoid. In this case the first operation consisted of dividing roots outside the dura. Pain was present on awakening. Forty-eight hours later, and without an anesthetic, the surgeon made an intradural section of the seventh and eighth roots, but the same kind of pain continued that he had had previously. An application of a blunt instrument to the posterior columns caused intense and widely distributed pain. After the final operation, the pain gradually ceased, and there was general improvement, with some anesthesia over the outer side of the arm from the deltoid downward across the neck in front to the center of the clavicle and behind to the center of the scapula. A degenerative neuritis was established by the microscopic findings. Seven or eight years after the operation the patient complained of drawing pain in his stumps with anesthesia as before over the deltoid. He resumed the morphin habit, which he had contracted early, so that the quality of pain could not be accurately estimated. Abbe records another case of spastic paraplegia with pain in the left leg and recurring muscular spasms. The four posterior lumbar roots and the upper sacral roots were divided. Pain disappeared, and anesthesia developed early, but the sensation returned. The patient died of apoplexy on the twelfth day.

Drs. Frank R. Fry and Sidney I. Schwab[3] of St. Louis reported a case of laminectomy for postsyphilitic nerve-root pain. A laminectomy of the third, fourth and fifth dorsal vertebræ exposed the cord, and after releasing the adherent dura, the fourth and fifth dorsal roots were severed. There was no opportunity to observe the presence or absence of sensation, as the patient died in a few hours. He was relieved of pain, however, during his conscious state.

Dr. John J. Thomas of Baltimore records a case of resection of the dorsal spinal nerve-roots for gastric crises in tabes with successful outcome.

Dr. Philip Coombs Knapp of Boston reports a case of tabetic pain in which Dr. Blake divided the seventh, eighth, ninth and tenth dorsal roots, with only temporary relief.

Dr. D. I. Wolfstein of Cincinnati records a case in which four roots in the dorsal region were divided for pain. There was an area of anesthesia corresponding to the definite root-areas, but no diminition of pain in these areas.

Dr. Charles H. Frazier[4] reports three cases in which he operated for spasticity and athetosis. The first patient was greatly relieved, and the second improved as to spasticity and athetoid movements, although of cerebral origin. The third case of spastic paraplegia was one in which the third and fifth lumbar and first sacral roots were divided on both sides. The spasticity was improved without loss of touch and pain sensation.

Dr. Spiller,[5] in 1905, advocated resection of the posterior roots for the relief of spasticities.

Frazier and Spiller[6] report one case.

Dr. Alfred S. Taylor of New York, who is an advocate of unilateral laminectomy, has, up to this time, performed seventeen operations, five of which were for pain.

Case 1.—The eighth cervical and first dorsal sensory roots were cut and the pain relieved over the distribution of the first dorsal.

Case 2.—Gastric crises in tabes. The seventh to the tenth dorsal roots were cut on both sides with prompt relief.

Case 3.—In a boy with painful spasms in the arm occurring every few moments, the upper half of the sixth and all of the seventh and eighth cervical and first dorsal roots were cut. Complete relief of pain and spasm was experienced, but some stiffness remained.

Case 4.—A simple laminectomy was performed without root-section, the patient experiencing much benefit.

Case 5.—Gastric crises with tabes. The seventh to tenth dorsal roots on both sides were cut. The results were uncertain, as the patient had been a morphinist and complained of severe pain after the operation.

Case 6.—A spastic and painful leg. The fourth and fifth lumbar and first sacral and part of the second sacral roots were sectioned on both sides, and relief obtained.

Dr. Charles A. Elsberg and his assistant, Dr. Beer, of the New York Neurological Institute, have cut the posterior spinal roots nine times during the past two years. In five of the patients, the operation was done for spasticity. There was great improvement in three of these patients, but only temporary improvement in the remaining two. In a case in which there had been an unsuccessful search for a spinal tumor by another surgeon three months before and which was later diagnosed as a case of lateral sclerosis, a double laminectomy was performed in July, 1910, for section of the posterior roots on both sides. The third and fifth lumbar and first sacral roots were cut, with the result that there was a marked relaxation of spasticity in the lower extremities for four weeks, and then a gradual return of spasticity in both lower extremities, with marked hyperesthesia over an irregular area,—the entire foot over the back and front and about two-thirds of the leg. This hyperesthesia did not follow the lines usually mapped out as supplied by the fifth lumbar root. There were no sensory disturbances following the operation. Death followed four months later from exhaustion. The autopsy showed a spinal tumor in the dorsal region.

Of the two last-mentioned patients, Patient 4 was operated on because of an old hemiplegic spasticity with athetosis. This patient's spastic upper extremity was much relaxed for about one month. Then the spasticity began to return and after six months was as marked as before the operation.

In the fifth patient, in whom only two roots were cut by Dr. Beer, some sensory loss was observed after the operation, much to the surprise of the operator.

Posterior-root section was done four times on account of pain. One patient had an infiltrating fibrolipoma of the cauda equina, which could not be removed. As she had suffered severe pain in the distribution of the fifth lumbar posterior root, it was divided on the left side, and she was entirely freed of her pain by root section.

In the second patient, in whom root section was done for pain in her upper extremity from a chronic spinal meningitis, a section of one-half of the seventh cervical, eighth cervical, and first dorsal produced sensory disturbance following the operation, and relief was not obtained from the sectioning.

In the third patient, a section of all of the posterior roots going to the left upper extremity was made for relief of the excruciating pain in an amputated extremity. An amputation of the wrist had been done for sarcoma of the hand, and a second amputation was done by a surgeon in an attempt to relieve the neuralgia which followed the first amputation. The pain in this case was not relieved by the section of the posterior roots.

In the fourth case several posterior roots were cut, among them the eighth and ninth dorsal, in order to relieve severe root pains, the origin of which could not be determined. No relief was obtained by the patient; and no anesthesia was noted after the operation. None of these cases died from operation.

The one case I reported is a fair illustration of the difficulties in making a correct diagnosis in intractable painful conditions. The differentiation between a peripheral nerve-trunk disease, tabes, and a painful impression from cerebral disorder is not always possible. This case creates, as do other cases similar in their symptomatology, a hesitancy in accepting the former conception of the sensory paths in the spinal cord.

The model diagrams compiled by many investigators are evidently subject to modification in different individuals, and it is fair to assume that the segments of the cord do not invariably preside over definite skin or muscle areas; neither can one be sure that two, or even three, segments contain the landing-stations for representation in the skin. In many of the cases reported in which excision of several posterior roots was done for pain or spasticity, anesthesias that correspond to old or recent diagrams failed to develop. One must expect any sort of surprise after posterior-root section: an unusual anesthesia, a slight approach to loss of sensation, a temporary but uncertain modification of sensation that is suggestive of the usual lines of distribution, a hyperesthesia perhaps, or no disturbance of sensation

whatever. The distribution attributed to certain nerve-roots is unreliable, as evidenced by my case and other cases already cited, and shows that, in certain individuals at least, the sixth cervical does not always receive sensory impression from the radial side of the hand and arm. The argument is advanced that in these operations the posterior roots are not thoroughly severed, but this criticism is not just and casts discredit on a skilled operator or observer. We might better admit that sensory impulses are received by the spinal cord through many segments and that the sensory pathway into the cord from the periphery is split up into many parts.

We may also be forced to admit that the pathway in the cord is not as uniform as we formerly held; that fibers for various sensations are scattered widely and have more than one representative column.

Karl Petren,[7] in an analysis of 96 cord injuries, shows that the sense of touch is represented in the posterior column of one side of the cord and in the lateral columns of the opposite side. This may explain, in a measure, why sensation is not always impaired or lost when posterior roots are sectioned. Dana holds that some of the sensory tracts, notably of pain and temperature, are located in the deep white tracts of the cord in front of the crossed pyramidal bundle. It is not improbable that the sensory pathway in the spinal cord is crossed and recrossed in its upward approach to the cortex and that this intricacy of lacing fibers may be so involved that it is impossible to determine accurately segmental receiving stations. Take, for example, the frequent failures to relieve permanently spastic muscles by root-section, granting also that the motor tracts are involved. In some of the cases reported, improvement lasted only from one to six months. Is the return of the spasm due to a repair or regrowth of the cut sensory roots, a condition emphatically denied by investigators; or may we assume that other segments, like collateral blood-vessels, take up the function of its injured neighbor; or are sensations conveyed into the cord by sensory fibers running in motor roots; or shall we go higher and consider the cortex of the brain and its memory of painful impressions?

Sherington has shown that cutaneous zones do not correspond numerically with the course of the ribs, but are, in general, much lower, and that each spinal root contributes fibers to several peripheral sensory nerves; yet the territory covered by a single root is never a patchwork, but an area.

Zabinski, in a case of ascending neuritis of one arm on which many operations had been performed, finally made an intradural section of the sixth, seventh and eighth cervical and the first dorsal and secured immediate relief from pain, which returned slightly in the second week and was accompanied by anesthesia up to the middle of the arm. This case proved the correctness of the old diagrams.

Abbe and Dana, following Féré's tables, have worked out the areas supplied by the sixth, seventh and eighth cervical nerves in relation to muscles and sensation. The sixth cervical supplies the latissimus dorsi, deltoid, teres major, pectorales, and the supra- and infraspinati; and it also carries sensation from the outer part of the shoulder, arm and forearm, and the radial distribution in the hand. The seventh cervical supplies the rhomboid, pectorales, latissimus dorsi, pronators, and triceps, and supplies sensation to the radial side of the forearm and hand.

The eighth cervical supplies the pronators, pectorales, flexores carpi et digitorum, hand muscles and triceps, and supplies sensation to the forearm and hand, and the ulnar and median areas.

The first dorsal supplies the flexores carpi et digitorum, pectorales and intercostohumerals.

No investigator has been able to divide the tracts in the cord that convey touch, pain or muscle-sense for the reason advanced earlier in the paper, namely, that these tracts are so scattered through the white substance of the cord that to separate them is impossible.

In some cases of intractable pains wherever located, we are obliged to fall back on the generally accepted theory that memory pain is the only possible explanation. In some of the cases cited and reported where pain has continued after an operation we are unable to advance any acceptable theory other than that the sensory cortex or other gray ganglia in the brain is the seat of the pain. A painful impression is permanently lodged in the centers of consciousness.

The following conclusions are for consideration:

1. Old and new chartings of sensory areas are variable and unreliable.
2. Each individual, according to circumstances, has an individual center for pain.
3. The segments in the spinal cord follow no definite order except when gross lesions are present, and even here we may be in error.
4. When the posterior roots are sectioned for pain, it may be necessary to divide more than three, perhaps as many as five roots, to accomplish relief.
5. In some instances, it is advisable to section one-half of several roots, or alternate roots, to abolish or diminish pain and spasm.
6. If this order is followed, there is less likelihood of disagreeable results, such as helplessness from greater or less loss of voluntary control.
7. Allow the patient to come out of the anesthetic and reopen the wound for further root section, in case pain persists.

513 Pillsbury Building.

ABSTRACT OF DISCUSSION

Dr. H. N. Moyer, Chicago: In view of the fact that operations have been recommended for root pains and that the symptomatic criteria for operations in these cases are still uncertain, we are indebted to Dr. Jones for a timely discussion of this subject. It is obvious that the difficulty is one of diagnosis; if the section of the root is made peripheral to the lesion, relief cannot be hoped for, and it is the indefiniteness of localization of sensory root lesions that makes an operation of this character uncertain, and should lead us to prefer other methods of relief where possible. During the last six months at the Cook County Hospital we have been treating tabetic root pains by the injection of cacodylate of sodium into the spinal canal, a method proposed by Dr. Heym. During the past six months we have injected upwards of thirty cases. In most of them there has been a prompt relief of pain; in one case of tabes involving the upper segments of the cord, the relief was quite as prompt as in the others in which the tabetic involvement was lower down. No untoward complications have followed the injections. In making them we use the ordinary technic for lumbar puncture, but allow just enough spinal fluid to escape to show that the needle is in the spinal canal.

Dr. W. W. Graves, St. Louis: I had the privilege of seeing the case reported by Dr. Jones, and was very much interested at the time because of the diagnostic problems involved. The individual had suffered for many years from pain and I unhesitatingly made the diagnosis that Dr. Fry had made before, that this was a case of tabes. This diagnosis was founded on unusually small and irregular pupils, which did not react well to light, on sensory loss about the legs, about the chest, and a slight sensory loss—at least I found it so—about the outer surface of the arms and in the distribution of the fifth and sixth cervical roots; not any more on the right side, where he had so much pain, than on the left. The peculiar problem in the case was that this individual who appeared to suffer from intolerable pain during the day could lie down at night and sleep without narcotics. So that I regarded this pain as partly "attention pain." Perhaps he did have true brachial crises at times; but I believe that which he called pain was not actually pain dependent on a definite lesion, but rather on some sort of a psychical process—undue "attention"—with which we are all familiar in certain cases. The individual was able to sleep and he could be diverted from his pain during the course of the examination. I put the patient to bed, isolated him, diverted him as much as I could from his trouble, gave him large doses of mercury, because he had never had a thorough systematic course of treatment, and he showed very decided improvement. After keeping him under observation for about five or six months, he went to Scotland and he wrote from the steamer that he had not been so free from pain for fifteen years and he expected to return to St. Louis practically well. The pain persisting the way it did after the nerve root section by Dr. Jones seems to me to substantiate the diagnosis that this pain was not due to a definite root lesion.

---

[7] Petren, Karl: Arch. f. Psychiat. Nervenkrankh., 1910, xlvii,

Now, I should just like to add a word about the application of nerve root sections in spastic states. Last October during the meeting of the German Neurologic Society in Berlin I saw results obtained by Foster's operation and the results achieved along that line are remarkable. In children who had never been able to walk or make any voluntary or purposeful movements with their legs, after relieving the spasticity by root sections and after training, those children were able to get around and get a great deal of use of their legs. As to the use of nerve root section for the relief of pain, I agree with Dr. Moyer that we shall resort to such serious operations less and less as time goes on.

Dr. Albert Abrams, San Francisco: As far as the localization of spinal root pain is concerned, there is one diagnostic point which has afforded me great service, and that is, if one takes the tender points peripheral to the supposed site of the lesion, and manipulates them by traction, pressure, or whatever the process may be, areas of tenderness develop at the vertebral exits of the spinal nerves which are segmentally related to the peripheral areas of sensitiveness, and if the vertebral areas of tenderness are frozen, the pain peripheral to the site of lesion disappears. All the *pointes douloureux* disappear.

Another point is to establish the site of lesion, whether peripheral or central to the exit of the spinal nerve. This fact can be readily determined by freezing; the pain disappearing if the lesion is at, or peripheral to the vertebral exit. Recently, freezing has been recommended for the relief of intractable pains incident to an attack of herpes zoster, and it has been said that there is nothing so specific for this condition. This method I recommended twenty years ago, and I found it in the majority of instances absolutely useless, for the reason that the seat of the lesion is in the spinal ganglia, that is, central to the exit of the spinal nerve roots. If, however, the lesion be at the vertebral exit of the nerve, all the pains are relieved. That is the reason why in tabetic patients we find little or no relief following congelation. Lately I have used injections of anesthetic medicaments at the spinal nerve exits for the purpose of determining whether by this means I could definitely decide whether the seat of the lesion was peripheral or central to the nerve exit. Thus far I have not arrived at any definite conclusion respecting the latter investigation.

Dr. E. D. Fisher, New York: A number of cases have been presented before the New York Neurological Society of section of the posterior spinal nerve roots, in cases of spastic paralysis, either of cerebral or of spinal origin by Drs. Taylor, Clark and Ellsburg. Most of these patients have done fairly well. Of course the class that I am now referring to has nothing to do with pain. Some of them have been returned to the society for observation six months or a year and a half afterwards. There is, however, only a limited degree of improvement.

One feature we have to deal with in that class of cases is that there is some mental impairment, and when we try the educational plan in such cases we are not so successful as we might otherwise be. I believe, however, in the operation for these spastic cases, but we must be particular in choosing them. In the conditions of pain I have found that it is more beneficial, as has been suggested, in the peripheral type. Tabetic pains or tabetic conditions, such as the gastric crises, and so on, have not been as successfully treated by these methods as the cases of a peripheral neuritis, and even in that class I would certainly advise all other forms of treatment first.

I will refer to one case, a patient who had spastic hemiplegia, in which the condition was so extreme that he preferred to have his hand removed to the continuance of the spasm. Following the operation neuromas formed on the ends of the nerves. They were removed but again returned. Several operations were performed, until the arm was removed at the shoulder-joint at the third or fourth operation. The pain again returned. The brachial plexus was then removed. The final operation was the section of the posterior spinal nerve root which resulted in permanent recovery, except that at times the man had pains which we thought were psychical rather than actual. This is the position which resection of the posterior nerve roots is in to-day. It seems necessary at times to resect four of the spinal nerve roots if we are to get the results that we wish, or even to get anesthesia following the operation.

PATHOLOGIC FINDINGS IN HYPERTENSION*

ROGER I. LEE, M.D.
Physician to Out-Patients, Massachusetts General Hospital; Visiting Physician, House of the Good Samaritan; Assistant in the Theory and Practice of Physic, Harvard Medical School
BOSTON

During the last ten years much has been written on the subject of blood-pressure and hypertension. Most of the work has been based on clinical findings; comparatively little has been done in the way of following cases to the autopsy table. There are, of course, grave objections to drawing deductions from a comparative study of blood-pressure determinations taken shortly before death and the pathologic lesions found at autopsy. At the same time it seemed that the study of a group of cases which had been followed to the autopsy table might be of interest.

All observers are agreed in regard to the frequent occurrence of hypertension in nephritis. Cushing[1] and others[2, 3] have shown that high blood-pressure occurs in cases with increased intracranial pressure. The chief discussion has been directed toward the question of the occurrence of hypertension in arteriosclerosis independent of a nephritis. Sawada[4] has never seen a case of hypertension over 170 in simple arteriosclerosis. Romberg[5] considers that persistent high blood-pressure in a suspicious case establishes the diagnosis of chronic interstitial nephritis.

The material reported in this paper consists of the pathologic findings in every case showing a systolic blood-pressure of over 160 in life which has come to

autopsy from the medical wards at the Massachusetts General Hospital from Jan. 1, 1907, to April 25, 1911. Before 1907 the blood-pressure determinations were not made in sufficient numbers to give adequate data. Since 1907, while blood-pressure determinations have not been used as a routine in every case at the Massachusetts General Hospital, yet it is fair to say that such determinations have been made in nearly every case, if not every case, that would come into the group under discussion.

Unfortunately, only the determinations of the systolic blood-pressure are available. The instrument used has been the Riva-Rocci apparatus with the wide armcuff. The observations were all taken in the recumbent position when the patient was able to lie down. The apparatus was placed on a table practically on a level with the heart, with the arm at the same level. The determinations were made by various individuals, but in general the method was that advocated by Janeway[6] and Sawada[4]; namely, the point at which the first full beat returns after the obliteration of the pulse. Janeway and Park[7] have shown that in clinical blood-pressure determinations, if the wide arm-piece be used and if the return of the first fully developed pulse-wave be taken, even advanced arterial thickening and calcification probably do not intrude an error of any importance.

The limit of 160 was taken, as Janeway[6, 8] and others[9, 10] believe that such a limit is rarely exceeded in normal individuals. From Jan. 1, 1907, to April 25, 1911, there were in the medical wards of the Massachusetts General Hospital fifty-three cases with blood-pressures over 160 that came to autopsy. The hospital admits only acute cases or acute manifestations of chronic cases. Most of the autopsies were done by Dr. Oscar Richardson; a few by Dr. J. H. Wright. The histologic examinations were made by Dr. Wright.

In the discussion of the diagnosis, little attempt has been made to balance the relative importance of the pathologic findings. If a kidney lesion of any description is present, it is considered that such a case belongs to the group of cases of hypertension associated with kidney lesions.

HYPERTENSION WITH LESIONS IN THE KIDNEYS

The pathologic findings showed some kidney lesion in thirty-eight cases, or over 71 per cent. These thirty-eight cases include one case which was, pathologically, acute degeneration of the kidneys and one case of hydronephrosis. In seven of the thirty-eight cases showing kidney lesions, or 13 per cent. of the whole series, the lesions found at autopsy were essentially confined to the kidneys (Cases 2, 8, 19, 36, 38, 42 and 53). Five of these seven cases showed pathologic changes classified as chronic glomerulonephritis, one as subacute glomerulonephritis and one as chronic interstitial nephritis. The maximum systolic blood-pressure in this group of seven cases ranged from 165 to 240.

HYPERTENSION WITH ARTERIOSCLEROSIS

Arteriosclerosis was found at autopsy in thirty-seven of the fifty-three cases, or 69 per cent. General arteriosclerosis was associated with lesions in the kidney in twenty-eight cases, or 52 per cent.

There was only one case (Case 46) of hypertension with arteriosclerosis in which there was no kidney lesion,

no cerebral lesion and no cardiac lesion, except simple hypertrophy and dilatation, the blood-pressure was 210. This case was in the hospital only twenty-four hours, and there was only one observation of blood-pressure. The patient was in coma. The urine showed no albumin but a slight trace of sugar. The pathologic examination showed a woman of 60 years, with slight general arteriosclerosis, a heart weighing 520 gm., normal kidneys weighing 268 gm. and no other lesions worthy of note.

In two cases (Cases 41 and 47) of fibrous endocarditis with no lesions in the kidneys, the valvular lesions were slight and the essential pathologic change seemed to be arteriosclerosis.

HYPERTENSION WITH CEREBRAL LESIONS

In eight of the fifty-three cases, or 15 per cent., there were definite cerebral lesions. One case was associated with a chronic nephritis and three with arteriosclerosis. In four cases no other blood-pressure-raising factor besides the cerebral lesion was apparent.

HYPERTENSION WITH CARDIAC LESIONS

In thirteen of the fifty-three, or over 24 per cent., there were definite cardiac lesions in addition to simple hypertrophy and dilatation of the heart, and in eleven of these thirteen there was endocarditis of the aortic valve. In every case in which the endocardium was affected, the aortic valve was involved. Three of the thirteen cases showed no other lesions which might be assumed to raise the blood-pressure.

HYPERTENSION WITHOUT KIDNEY LESIONS

There were fifteen cases, or 28 per cent. of the series, in which no kidney lesions were found; at autopsy seven showed cerebral lesions. In four cases the chief pathologic lesion was cerebral hemorrhage. The blood-pressure varied in these four cases from 175 to 260. In one case (Case 16) the cerebral hemorrhage was traumatic; in that case the blood-pressure was 175. In the other three cases (Cases 21, 22 and 48) the cerebral hemorrhage was apparently due to the rupture of an arteriosclerotic cerebral vessel. In these three cases, the blood-pressures were over 200. In the same group is one case of brain tumor (Case 33) with a blood-pressure of 190; one case of degeneration in the pons (Case 43) with a blood-pressure of 175, and one case of miliary tuberculosis with a tuberculous meningitis (Case 31) with a blood-pressure of 165. Consequently, in seven out of fifteen cases of hypertension not associated with a lesion in the kidney, there was some cerebral condition which might have caused cerebral pressure. Cushing and others have shown the relation between increased intracranial pressure and an increased blood-pressure.

In this group of fifteen cases of hypertension without kidney lesions, seven showed cardiac lesions. There were two cases (Cases 10 and 44) in which intracardiac thromboses were found without other cardiac lesions beyond simple hypertrophy and dilatation and without arteriosclerosis. There was one case of syphilitic aortitis (Case 25) with a slight amount of fibrous endocarditis of the aortic valve. In addition, one finds in this group four cases (Cases 41, 45, 47 and 52) of fibrous endocarditis of one or more valves of the heart, all associated with arteriosclerosis and one case with primary pernicious anemia. The aortic valve was affected in every case. In the same group of fifteen cases of hypertension without kidney lesions comes the case of arteriosclerosis (Case 46). In this group of fifteen cases of hypertension without lesion in the kidneys there were seven patients under 50 and eight over 50 years. The maximum systolic blood-pressure varied from 165 to 260.

HYPERTENSION WITHOUT LESIONS IN THE KIDNEYS AND WITHOUT ARTERIOSCLEROSIS

There were seven cases with neither arteriosclerosis nor nephritis. Of these seven cases four showed cerebral lesions. One was a case of brain tumor (Case 33), one was a case of general miliary tuberculosis with tuberculous meningitis (Case 31), one a case of degeneration in the pons and carcinoma of the ovary (Case 43), one a case of cerebral hemorrhage due to trauma (Case 16). The remaining three cases in this group were cardiac cases (Cases 10, 25 and 44). The ages in this group were from 30 to 52. This group of seven cases is characterized by a moderate degree of hypertension as a rule, two showing a maximum systolic blood-pressure of 165, one of 170, two of 175, one of 190 and one of 200. Therefore, in this series of fifty-three cases in the absence of both arteriosclerosis and any lesion in the kidney no blood-pressure over 200 was found.

If one considers only the cases with more than one blood-pressure observation and only cases showing constantly a blood-pressure of 200 or over there were ten cases all of which were cases with kidney lesions. In nine of these ten cases arteriosclerosis was also present, although in two cases the arteriosclerosis was slight.

Of fifty-one cases in which we have the kidney weight twenty-nine, or 56 per cent. +, were distinctly atrophic i. e., weighing under 250 gm. Of the twenty-nine kidneys weighing less than 250 gm. twenty-seven showed kidney lesions and two showed no kidney lesions. One case (Case 31) showed miliary tuberculosis in which the blood-pressure was 165. In this case the kidneys weighed 208 gm. but the heart also was small, weighing 223 gm. The other (Case 48) showed arteriosclerosis and cerebral hemorrhage. The blood-pressure varied between 260 and 125. The heart weight was 335 gm. and the kidneys 190 gm. Only eleven cases of the thirty-seven with kidney lesions, or 27 per cent., failed to show small atrophic kidneys. Of the ten cases with kidney lesions, with kidneys weighing more than 250 gm., five showed kidneys weighing 250 to 300. Histologically, all showed atrophic conditions. In one case, with kidneys weighing 313 gm., the chronic interstitial changes were slight (Case 9). This was the case of lead poisoning and pneumonia. Three of the other four cases were cases of subacute glomerulonephritis and the other was a case of acute glomerulonephritis. In seven of these ten cases the blood-pressure was over 200 mm. of mercury. Marked hypertension occurs in this series in a certain number of cases in association with kidneys which are not atrophic, and in acute and subacute glomerulonephritis.

The weights of the hearts were of considerable interest; of the fifty-one cases in which the heart weights were recorded only thirteen weighed less than 400 gm., ten weighed between 400 and 500, and twenty-nine, or 56 per cent., weighed over 500 gm. Of special interest is Case 48, in which the heart weighed 335 gm. In this case a blood-pressure of 260 was present for twenty-four hours, of 180 the next twenty-four hours, but the pressure sank to 125 on the third day, the day of death. Case 12 was observed for two weeks, with three observations scattered through the period. The blood-pressure varied between 225 and 190. The heart weighed 363 gm. Consequently, a high blood-pressure of over 190 may persist for a period of days with only a very moderately hypertrophied heart.

The anatomic and clinical diagnoses approximately correspond in forty-four of the fifty-three cases. In five cases (7, 9, 27, 49 and 50) kidney lesions were found at autopsy, but were not diagnosed in life. In one of these five cases (Case 9), one of lead poisoning with lobar pneumonia, the kidney lesion was slight. In two cases (7 and 27) the nephritis seemed incidental. In five cases (22, 25, 30, 41 and 46) a kidney lesion was diagnosed but was not found at autopsy. This diagnosis was, apparently, based chiefly on the high blood-pressure.

In these fifty-three cases albumin was absent in only four; in three of these four there was no kidney lesion. In these four cases the clinical diagnosis of nephritis was made twice and in one the kidney lesion was present and in one a kidney lesion was not present at autopsy.

Of the fifty-three subjects thirty-six were males and seventeen females. The males predominate over two to one. In the ten-year periods there were one from 20 to 29, nine from 30 to 39, nineteen from 40 to 49, ten from 50 to 59, nine from 60 to 69, five from 70 to 79 and one subject of unknown age.

The age period of from 40 to 49 has nearly twice as many as any other period. From 40 to 59 are twenty-nine cases, or 54 per cent., of all the cases. The youngest patient was 25, the oldest 73.

SUMMARY

Some kidney lesion was present at autopsy in over 71 per cent. of the cases of hypertension. In 13 per cent. the kidney lesion was essentially uncomplicated by other possible blood-pressure-raising factors; the lesion in the kidney was atrophic in 72 per cent. of the kidney cases. Hypertension also occurs in the so-called acute and subacute glomerulonephritis as well as in the atrophic form of nephritis. Arteriosclerosis was present in 69 per cent. of the cases, but in only one case could all other lesions which might cause hypertension be excluded.

In fifteen cases no kidney lesion was found at autopsy. Seven of these cases presented cerebral lesions, seven cardiac lesions and one general arteriosclerosis. In every case of valvular disease of the heart, the aortic valve was involved. No patient without either nephritis or arteriosclerosis showed a blood-pressure of over 200. All the patients with repeated and constant blood-pressure readings of over 200 showed some kidney lesion.

In thirty-eight of the fifty-one cases there were definitely hypertrophied hearts, yet in some instances high blood-pressures were observed to persist for days with hearts weighing less than 400 gm.

The following conclusions seem justified:

Hypertension occurs most commonly in association with some lesion in the kidney. The most common lesion is an atrophic kidney with increase of connective tissue and disappearance of glomeruli. Hypertension occurs also in association with acute, subacute and chronic glomerulonephritis.

Hypertension occurs not infrequently in association with cerebral lesions.

A moderate degree of hypertension may occur in cardiac lesions. In valvular cardiac lesions the aortic valve is apparently always involved.

Hypertension may occur rarely in cases of general arteriosclerosis without other lesions.

With a continued systolic blood-pressure of over 200, some form of nephritis is found.

Hypertension usually indicates well-marked cardiac hypertrophy. The hypertrophy may be moderate in connection with a well-marked hypertension over a considerable period.

ABSTRACT OF DISCUSSION

DR. WILLIAM OPHÜLS, San Francisco: I was much interested in Dr. Lee's paper, because lately I have been working on the same question, but from an anatomic point of view. I should refer those of you who are interested to the Scientific Exhibit, where some microphotographs and charts are exhibited, which show the result of an investigation of kidneys, heart and blood-vessels in 1,000 consecutive autopsies. As is shown in these charts, general arteriosclerosis and the so-called small granular kidney are closely associated. Glomerulonephritis proper, however, can be distinctly separated from these primarily arteriosclerotic cases.

Dr. Lee's clinical observations bear out very closely what I have seen anatomically. In regard to hypertension I am inclined to place more importance on general arteriosclerosis than on the renal lesions which may be associated. I was quite astonished myself, in looking over my cases, to learn how comparatively insignificant the renal lesions are in producing the symptom-complex. Undoubtedly at present the rôle of the kidneys in its production is greatly exaggerated.

DR. EDWARD F. WELLS, Chicago: There is an art, as well as a science, in the study of blood-pressure, and the art, to be useful, requires practice. He who measures the blood-pressure rarely and in the exceptional case and attempts to draw conclusions from his occasional observations, places himself in the position of one who would form his opinions on the pulse under similar circumstances; both would obtain very *indefinite and obscure impressions of the* great variations in the characteristics of the blood-pressure and pulse, respectively, and would underestimate the value of the procedure. He, however, who measures the blood-pressure as a diagnostic routine procedure obtains useful and pertinent information.

The blood-pressure which rises gradually through a long period of time and is accompanied by cardiovascular and nephritic morbid changes, is probably fundamental and permanent, and is one which cannot be materially reduced, and it may be questioned whether this should be attempted. There is, however, an exalted blood-pressure which attends certain toxic conditions, as, for example, the toxemia of pregnancy, which results in eclampsia, in which the blood-pressure may rapidly rise to great heights. Although we do not yet know fully the relations of the blood-pressure to the toxic agent in these cases, nevertheless we are justified in regarding it as due to the rapid introduction into the circulating liquids of a powerful toxin which acts with intense energy on the vasomotor nerves. Such high blood-pressures quickly fall on removal of the offending cause; they are clearly functional. Now in the class of cases first alluded to, there may be added to the ordinary high blood-pressure of the individual a more or less rapidly advancing increase in tension, due to some ephemeral toxemia, and which may disappear with celerity when once the extra burden is removed, leaving the blood-pressure at the usual high level for the individual, but the reduction, is not materially lower than is habitual for the patient. It is my belief that the recognition of these facts is of practical importance, first, to the patient's welfare, and second, to the fair fame of medicine.

Dr. Frank Billings, Chicago: What has been said regarding cardiovascular changes, agrees with the statement already made that the cardiovascular or vascular changes with the hypertrophy of the heart are very important things to consider in blood-pressures. Sometimes in our ignorance the elevation in the blood-pressure is ascribed to a toxemia; there seems to be nothing else which will describe it. However, toxemia has been recognized in many other conditions in which there is an increase of blood-pressure; some vasomotor process such as is exemplified in the phenomena which appear in hyperthyroidism. In the early stages of this disease there is a blood-pressure of 180 or 200, and this is before the disease has progressed to changes in the cardiovascular system. This must be the result of a toxemia, something which produces overfull blood-vessels. As Dr. Wells stated in relation to the management of such conditions, the existence of a permanent blood-pressure is in a sense conservative; it is Nature's method.

We must consider hydrostatic pressure, but there is another condition, toxemia, which we must not neglect. I agree with Dr. Lee that there are many other things that cause hypertension, such as cardiovascular changes and other changes referable to the kidney. I have watched many cases in the clinics, many that have gone to autopsy; I have seen patients suffering from toxemia without apparently any cardiovascular changes; but at autopsy the kidneys were found to be practically worthless, or functionless.

Just one other word. I do not believe that we can say definitely that there is an exact dividing line between the pathologic and the normal in these cases. To say that 160 is the limit of health, or the point at which disease begins, I think is wrong. There are people of the very nervous type who, under certain conditions, such as overwork, worry, and the like, run up the point to 160, 170 or 180, even, and here we find associated the toxemia that goes with fatigue. When these people are treated with ordinary hygienic measures there is a lessening in the blood-pressure. I do not believe that we have any right to have a statement go forth that a blood-pressure of 160 or more really means, necessarily, disease.

Dr. C. F. Hoover, Cleveland: For the past few years I have studied the diastolic arterial pressure in all suspected cases of hyperthyroidism and I have yet to find a patient in whom there is an elevation of the diastolic pressure even when the systolic pressure is high. My attention was attracted to this point by cases with cardiovascular disease being referred to the surgical wards for operation on goiter which these patients happened to have. The goiters in such cases were merely incidental and were not the cause of the cardiac symptoms.

Dr. Charles L. Greene, St. Paul, Minn.: With respect to the findings in these cases of aortic lesions, in the cases that have been so ably described by the reader of the paper, if the cases were in fact aortic regurgitation, then what has been presented should not be included among the high-pressure cases. The experience of all of us who are doing this sort of work shows that we may get a very high systolic pressure, but for different reasons, as described by Dr. Hoover. With the Corrigan pulse we may find a high systolic pressure and a very low diastolic pressure.

Dr. Walter L. Bierring, Des Moines, Iowa: I should like to ask the reader of the paper if any histologic examination of the brachial artery was made and compared with the condition of the other arteries in the body. It has become recognized that marked differences often exist in the pressure in the brachial and the femoral arteries, and it would be interesting to know if local changes in the blood-vessels could account for this difference.

In determining arterial pressure by the simpler method of palpation, it has also seemed to me far more satisfactory to palpate the femoral artery rather than the radial or the brachial, and by comparative tests one can make much closer estimates in this way with the findings of different forms of special apparatus used for this purpose.

Dr. Roger I. Lee, Boston: Only a macroscopic examination of the adrenals was made in these cases. No gross lesions were found. Among these cases was one of syphilitic aortitis. The spirochetes were found in the walls of the aorta. Two or three other patients gave a history of syphilis.

Only rarely were histologic examinations of the blood-vessels made. The brachial artery was the one used, as a rule to ascertain the blood-pressure. The femoral artery was occasionally employed, but merely as a control for the brachial artery. But in the synopsis the conclusions were drawn from the results obtained from the brachial artery.

I agree with Dr. Billings in regard to setting a limit, or trying to set a limit between what is pathologic and what is normal; the limit of 160 was merely taken because we wanted some limit and 160 is generally regarded as being a fairly good dividing line. It is evident that the diastolic blood-pressure may be very variable in these cases; a further study will result, no doubt, in more satisfactory conclusions.

The cases studied include only one case of frank aortic regurgitation, and one case of aortic stenosis.

The primary purpose of my paper was to find out how great a rôle arteriosclerosis played in hypertension, inasmuch as the German schools have insisted on the close relation between hypertension and kidney lesions. It should be remembered that kidney lesions, however slight, may be sufficient to cause a high blood-pressure. It is certainly very difficult to balance the relative importance of the different lesions. One must think of the so-called latent nephritis, a name applied by the Germans. In this study I classified all cases having any kidney lesions under the head of hypertension associated with kidney lesions.

Another reason for my undertaking this study was that I wished to place hypertension on an anatomic basis so far as possible. While as yet few cases of hypertension have been recorded as the result of a toxemia, it is certain that soon many will be. Barker has reported a case of transitory high blood-pressure in a case of tabes with gastric crises. These cases must be carefully studied, especially in regard to the condition of the heart, kidneys and blood-vessels.

RESERVE RENAL CAPACITY IN CHRONIC INTERSTITIAL NEPHRITIS*

EDWARD F. WELLS, M.D.
CHICAGO

In the mid-course of chronic interstitial nephritis, with the secreting structures of the kidneys greatly reduced by degenerative and atrophic processes, more or less marked renal insufficiency is the rule. With the high-pressure circulatory balance well maintained, the urinary water flows in full or increased volume, the insufficiency being confined to an inadequate excretion of certain waste and superfluous determinable and occult substances which are deleterious to the human body, and which are ordinarily efficiently removed by healthy kidneys. It is probable that the most toxic and important of these are, as yet, demonstrable only by their effects. In the future, when methods shall have been perfected whereby these may be differentiated and measured, our problem will be susceptible of ready and accurate solution. For the present, and for our practical purposes, we are compelled to rely on the amount of urea, chlorids, phosphates and sulphates contained in the daily urine, together with the general and special symptoms, in forming an estimate of renal capacity. Notwithstanding the difficulties and inaccuracies attending such estimates under current conditions, it is my opinion, based on a fairly long and broad experience, that they are of sufficient diagnostic and prognostic importance to warrant their employment in the routine of general practice.

---

* Read in the Section on Practice of Medicine of the American Medical Association, at the Sixty-Second Annual Session, held at Los Angeles, June, 1911.

Many years ago I attended a man who was known to have had chronic interstitial nephritis for more than twenty years, during the latter of these accompanied by frequent and at times very severe attacks of uremia. For several years fairly full analyses of the urine were made once or twice a week, and at times daily for periods of from two to six months. These analyses showed the total solids and urea uniformly greatly reduced, the latter ranging from 3 to 12 gm. per day, with 8 gm. as an approximate average. At one time the daily excretions of urea averaged about 5 or 6 gm. over a period of several weeks, at the end of which the patient had a severe attack of uremia with most active maniacal excitement. During twenty-four hours of violent muscular exertion he passed urine which contained 36 gm. of urea. Following this observation it was noted that active, and to a lesser degree passive, muscular exercise regularly increased the excretion of urea, and approximately a like amount of such exercise always augmented the urea excretions to a corresponding degree; that is, up to from 10 to 12 gm. Later it was experimentally demonstrated that if lean meats were added to the diet, the urea excretion was further increased according to the amount of proteid ingested, up to 15 or 20 gm. This required about 300 gm. of meat. In this case it was clearly evident that beyond this proteid intake the urea output lagged behind. For reasons not material to our theme these observations, so far as the giving of meats was concerned, were omitted, but the employment of active and passive muscular exercises were continued with satisfactory results as an important feature of management. In this case the conclusion to which I had come, and which was shared by other physicians, namely, that the secreting structure of the kidneys were so largely destroyed as greatly to reduce the renal functional capacity, using the urea output as a measure, to far below the requirements of the system, and with a practical abolition of any reserve capacity, was demonstrably erroneous.

During the past ten years I have had frequent opportunities to pursue these investigations, with the result that a sufficient array of facts has been accumulated to warrant the deduction that, in the class of cases under discussion, the kidneys are seldom anatomically or functionally altered to such degrees as to preclude the moderate regular excretion of water, urea, chlorids, and other of the measurable constituents of the urine, and, on occasions of great and extraordinary stimulation, to show evidence of correspondingly increased functional activity, which may, with propriety, be termed reserve renal capacity. That this is an important fact, capable of being turned to diagnostic, prognostic and therapeutic usefulness, must be clearly evident.

In investigating the capacity of the kidneys in chronic interstitial nephritis under the ordinary conditions of life, and under those entailing extraordinary stress on all the organs engaged in the production and excretion of the urinary constituents, various procedures may be adopted, varying with the character of the information desired, and, it may well be added, with the predilections of the physician.

The conditions under which the excretion of urinary water may vary are so fully dealt with in the literature that only a few points of practical importance will be considered: As is well known the urine is, as a rule, notably increased in quantity, with a very considerable proportional and total reduction of the urea and other solids. Should the volume of urine decline, without a corresponding reduction of liquid intake, further examination will disclose circulatory failure with occult or manifest edema. Much later, when there is added to the above high color and increased or even largely increased total urea excretion, cellular nutritive balance with destructive metamorphosis will be present. Observation will soon show that at neither the highest nor lowest output of urinary water does the excretion of urea and other solids reach the highest level; but rather is this found at some intermediate point, which, because of its therapeutic importance, should be, from time to time, closely determined.

During the recently passed years the excretion of chlorids has been very closely studied, and I have only a word to add in this connection, namely, that as a foundation for any dietetic directions which intelligently consider this question, there should be a fairly accurate determination of the chlorid excretory capacity of the kidneys. The methods may be readily adapted.

In the present state of our knowledge in chronic interstitial nephritis, and in connection with our theme, greatest interest lies in estimating, comparatively and absolutely, the excretory capacity of the kidneys for those nitrogenous substances resulting from proteid metabolism of which urea is the chief and best known.

For the purpose of obtaining information as to the renal capacity, I am in my own practice accustomed to employ the following procedures:

The daily urine is examined closely, and recorded and charted every day during the entire time occupied in making the observations, which is divided into a series of periods of three days each. During the first of these the patient is under his accustomed diet and regimen. During the second he takes two freshly made pills of mercurial mass every night, followed by a saline cathartic next morning. In the third the diet is restricted to water, cream and water soups and thin gruels, all in moderate or small quantities, with physical rest. During the fourth he has added to his diet breads, rice and potatoes, the food having a daily caloric value to meet fully nutritional requirements. To this there is added 300 gm. of lean meat during each of the three days of the fifth period; 400 gm. in those of the sixth; 500 gm. in those of the seventh; 600 gm. in those of the eighth. If desirable, the series with increasing amounts of proteid intake may be further extended if required.

In giving the meats in this gradually ascending scale, it will be noted that during the earlier periods the urea excretion rises directly as to the proteid ingestion. As the scale ascends, however, there comes a time in which ingestion of proteids and excretion of urea no longer run parallel, the latter lagging behind; later this becomes so marked that I prefer to terminate the investigation.

Applying the rule of averages, to which no chronic interstitial nephritic patient very closely conforms, the daily excretion of urea by the three-day periods may be tabulated as follows:

Period 1, under ordinary diet and regimen	12 gm.
Period 2, under ordinary diet, etc., with evacuants	8 gm.
Period 3, under very restricted diet and rest	6 gm.
Period 4, under full carbohydrate diet plus 300 gm. lean meat	14 gm.
Period 5, under full carbohydrate diet plus 400 gm. lean meat	22 gm.
Period 6, under full carbohydrate diet plus 500 gm. lean meat	30 gm.
Period 7, under full carbohydrate diet plus 600 gm. lean meat	36 gm.

If during the fourth and subsequent periods the patient subjects himself to unusual active and passive muscular exercise, the urea output should be considerably augmented. Should there be any material deviation in a downward direction, from the curve of urea output, based on the above, a corresponding renal incapacity is indicated; any excess above that of the first period which may be observed during periods of four to seven, inclusive, represents reserve renal capacity.

In making these tests, wide variation in methods, and in additions to or subtraction from the details of those mentioned, may be practiced, as required, or as individual experience demonstrates to be the most available. Special emphasis, however, should be laid on the character of the proteid given, inasmuch as the urea output after the ingestion of meat follows fairly promptly and reaches its full height on the second, certainly on the third, of these days, whereas should eggs be employed, a much longer time is required for elimination. There may be added during these last three days as much active and physical muscular exercise as the patient is able to bear, which will further increase the output of urea. Personally, I prefer to make this a fourth three-day period, but this is probably immaterial.

As an example of the wide variations met with in making these estimations, the following case is worthy of mention. A few years ago a gentleman, 65 years of age, with chronic interstitial nephritis of many years' duration, passed, under great urinary stress, urine which contained during one twenty-four-hour period 64.5 gm. of urea. In making several tests, such as those described, the urea with great uniformity rose to from 30 to 35 gm. per day, and if much exercise should have been taken during the final period 35 to 40 gm. were not uncommon.

In making these tests from time to time, other important features were noted. For example, it was noticed almost constantly that, following the test, the patient appeared to be very much improved over his former condition. Most of this improvement was of such a nature that it could not be definitely measured. The patient, however, appeared to be fully aware of the fact, and indefinitely I shared his opinion. For this reason I have made these observations with more or less frequency in each patient for the purpose of obtaining, first, diagnostic and prognostic information; second, for possible therapeutic advantages; and third, that the patient's interest in his case and its management may be intelligently and optimistically maintained.

It is a fair inference that, if known, the output of urea can by simple measures and with safety be so stimulated that from an average of 10 to 15 gm. per day, an amount double this may be uniformly reached: the anatomic alterations and physiologic capacity are such as to eliminate urea, chlorids, phosphates, sulphates, etc., with fair safety. The danger to these chronic interstitial nephritics must, then, lie in the failure of the kidneys to eliminate other toxic substances of a nature so subtle as so far to defy analysis. It is also probable that the circulatory, and especially the extravascular circulatory changes are responsible for the failure to eliminate these heretofore undefined toxic agents. From this it may be readily seen that such measurements as those described fall far short of our requirements. Nevertheless, they are, taken in connection with such other observations as those of estimating the blood-pressure, the retinal fields and a careful review of the symptomatology, the best obtainable at the present time. As the results of my own observations, I am of the opinion that those cases in which there can be demonstrated, with regularity, a fair or large reserve renal capacity offer the best chances for prolonged life, physical and mental capacity and usefulness, while those in which the reserve renal capacity is but slight are in much greater risk of prematurely encountering the various serious accidents which accompany the later stages of this malady.

On the information obtained may be based some important details of management. In my own practice I advise such active and passive muscular exercises as may be taken without evidences of urea retention. Also the amount of proteid ingestion, always small or moderate, is gauged in like manner. These I consider points of great practical importance.

Along similar lines estimations may be made of the capacity of the kidneys to eliminate urinary water; also of chlorids. The latter, taken in connection with observations on the weight of the patient and of the extra-vascular serum accumulation, blood-pressure and cardiac hypertrophy, is of prime importance and should be made with regularity. It is not my purpose, however, in this paper to consider this line of thought; my main object is to stimulate further and more accurate investigation.

4744 Woodlawn Avenue.

ABSTRACT OF DISCUSSION

DR. FRANK BILLINGS, Chicago: What Dr. Wells has read to us this morning should be a lesson; what he has given us has been an individual study of a diseased organ, the kidney, and there is much that is new in it. The method he employs in estimating the functional capacity of the kidney is interesting; perhaps if one wished to offer a criticism one might say that one could not, by such measures as he employed, fully estimate the physiologic function of the kidney, or the metabolism of the body; yet clinically the measure he employs is the only one that is practical by which we can reach any such conclusions. The painstaking way he has worked with the different diets, day after day, and all before he has arrived at any conclusion, shows that his work and study is worthy of careful consideration. He is using the same methods we should use in other diseases, such as diabetes—measuring the individual capacity of the patient.

DR. WALTER L. BIERRING, Des Moines, Iowa: The thought arises whether the disturbances in the nutritive balance may not be influenced by other organs besides the liver. In considering the condition termed chronic nephritis, a very close relationship was recognized between that triad of structures, the myocardium, the blood-vessels and the kidneys. It is also exceedingly difficult to estimate the functional capacity of the kidney, to note only the urinary findings; and oftentimes many of the symptoms which are most indicative of chronic nephritis are those of retention phenomena. The prognosis in chronic nephritis is dependent largely on the condition of the myocardium, and it appears to me that possibly in our efforts to preserve this reserve force referred to in the paper, we really bring about a condition more favorable to the myocardium or myocardial function; whenever we bring about such a condition by means of proper diet or otherwise, it tends to lower arterial pressure, lessen the strain on the heart, the retention phenomena become less marked, and a better functional ability of the kidney is brought about.

DR. EDWARD F. WELLS, Chicago: My paper illustrates the futility of attempting to make a suitable presentation of an important subject in the short time allotted; therefore I limited my remarks mainly to a consideration of certain tests for measuring the reserve capacity in chronic interstitial nephritis, with a well-preserved circulatory balance. In a few words I mentioned the fact that under certain circumstances, especially with a failing circulatory balance and a consequent nutritional disturbance, the tests mentioned are inapplicable. It must be clearly apparent that the tests mentioned are crude, but, rudimentary as they are, the methods are those which I have found available and useful for testing the urinary capacity of my patients. To these there should be added a study of the functional capacity of all the organs engaged in the preparation for urinary excretion. Those presented I should be pleased to have considered simply as a beginning of work along these lines, with the confident expectation that, intelligently practiced, they will be found as useful in the malady mentioned as are similar procedures in the study and management of diabetics. My object has been to extend our diagnostics—making a therapeutic and a prognostic diagnosis, if you will allo wthe terms; nevertheless, certain beneficial therapeutic results were obtained from the tests employed. However, I do not wish to lay any undue stress on this point.

TREATMENT OF DIABETES MELLITUS *

A. J. HODGSON, M.D.
WAUKESHA, WIS.

It is impossible in a paper of this kind to consider more than the most important points in the treatment of diabetes mellitus. The various special treatments that have been recommended for this condition cannot be discussed. A bibliography will be appended, but no attempt will be made to give any extended references to the many excellent papers that have appeared on the subject. The object of this paper is to call attention to certain well-defined principles which must govern the treatment of this serious and stubborn disease, if any satisfactory outcome is to be hoped for.

While this paper deals only with the treatment of diabetes, it is necessary for purpose of clearness to refer briefly to the etiology of the disease. A small percentage of cases are caused by some severe pre-existing pathologic condition that removes them from consideration in a paper of this kind. Such cases are those due to carcinoma of the pancreas, to syphilis, etc.

The cases that will be considered in this paper and which make up approximately 90 per cent. of all those exhibited by the patients that present themselves, are due to what may be called errors of metabolism. To assign this as a cause, however, is not to explain, for there are causes operating behind these metabolic errors. A careful study of the habits of a large number of diabetics convinces me that one of the most fertile causes of diabetes mellitus is a long-continued toxemia or auto-intoxication due to gross errors in eating. There are, of course, other causes: oft-repeated emotional excitement, the excessive use of starches or of alcohol, arteriosclerosis, that undefinable something which, for want of a better name, we call the gouty diathesis; heredity, sometimes associated with exophthalmic goiter—all these seem to play a part in the etiology of this disease; but by far the most important cause is the one first given, errors in diet.

WHAT CONSTITUTES A CURE

It should be impressed on the patient that a "cure" of this disease is not possible in the sense in which he understands a "cure," viz., that after the glycosuria has been overcome he may go back to his old habits of diet. He should be told that after his apparent recovery, continued care in eating is essential to his continued health. As well might a consumptive in whom the tuberculous process has been arrested by careful treatment expect to go back to foul air, insufficient light and lack of nourishing food and remain well, as a diabetic to keep his urine sugar-free while violating the very dietetic rules the disregard of which brought on his trouble.

DIETETIC ERRORS A FREQUENT CAUSE

In the past twenty years I have treated somewhat over 1,100 diabetic patients. A careful study of these cases has impressed me with the fact that the great majority of patients who suffer with this disease do so because, through ignorance, they have grossly abused their systems with the quantity, quality and kind of food used. Too much food, bolting the food so as to preclude proper insalivation, reading, thinking deeply or worrying while eating, using uncooked or but partly cooked starches—all these are contributory causes to that deranged metabolism which exhibits itself as diabetes. Particular stress should be laid on the viciousness of the prevalent habit of using large quantities of carbohydrate foods in which the starches are practically in an uncooked state, baking-powder biscuits, batter cakes, corn-bread, waffles, various forms of crackers—especially the Graham cracker, so largely eaten under the mistaken idea that it has an extraordinary food value—all these forms of starchy food are bad and contribute in no small degree to recruit the increasing army of diabetes. These causes will be taken up in greater detail as the treatment of the disease is considered.

The value of any treatment for any disease must be judged by results. And the results must have been obtained not in a few isolated cases but in a long series of cases. In order to make clear whether the treatment about to be described is worthy of consideration a table is appended of the cases of all the patients treated from May 1 to Dec. 1, 1910, giving the age of the patient, the duration and severity of the disease and the result of the treatment.

This table, of course, is but the briefest of outlines and is intended only to emphasize the results of the treatment. While more or less complete histories of more than 1,100 cases could be given, such a tabulation would be out of place in a paper of this kind. Before closing, a typical case-history will be given in detail with the treatment.

OBJECTIVE POINTS IN TREATMENT

In treating the class of diabetics with which this paper deals there are four objects to be kept in view:

1. To free as nearly as possible the blood and other tissues from sugar; to do this it is necessary—
2. To find the individual patient's tolerance for carbohydrate and if possible to increase that tolerance;
3. To find a diet that will furnish the necessary calories without, at the same time, increasing the sugar intake; and
4. To prevent, by dietetic or other measures, the constipation with which the majority of these patients suffer and which increases the toxemic condition.

The first thing to impress on the patient is the fact that this disease—in the class of cases under consideration—is one that possibly has been years in developing and that it is useless and hopeless for him to expect to obtain any relief in a short time. The changes which a long-outraged system has undergone are such as cannot be remedied in a week or a month. In diabetes, more than in almost any other disease (unless it is tuberculosis), the help and cooperation of the patient is absolutely essential to successful treatment.

FUTILITY OF DRUGS

Another fact to be emphasized is the futility of drugs in the treatment of this disease; futile, because harmful habits cannot be cured by drugs. A large percentage of the patients who present themselves bring with them

their bottles of codein and that worse than useless nostrum, Arsenauro. It is an unfortunate fact that many physicians still seem to harbor the belief that arsenic when prescribed under a proprietary name possesses virtues not to be found in the official preparations and, moreover, that it has lost the dangerous qualities inherent in it. I have seen so many patients with the codein habit and aggravated cases of constipation superimposed on the diabetes, and so many with wrecked digestive systems due to the long continued use of Arsenauro and other arsenic solutions, that I must utter a word of warning against the use of these drugs.

Too much stress cannot be laid on this point. Codein and arsenic may have their uses in a limited number of cases, but in the great majority of cases they should be left severely alone. If these drugs were merely worthless, there might not be any serious objections to their use, but they are a positive detriment and their continued use lessens the patient's chances of recovery. Not only that, but whenever a drug is given to a diabetic he is usually less careful in his method of living than if he realizes that his recovery depends on diet and hygiene alone.

QUANTITY OF FOOD IMPORTANT

One other essential must be made plain to the diabetic and that is the quantity of food eaten is just as important as the kind of food. Too often the patient suffering with diabetes is told to purchase gluten flour or gluten breads (most of which are frauds), and no limitation is put on the amount of these products that may be eaten. It is a fact that many mild cases of diabetes will show a diminution of sugar in the urine almost to the vanishing point when the patient is merely compelled to eat a very moderate ordinary diet. That is to say an antidiabetic diet is not always necessary to reduce the glycosuria; a reduction in the amount of ordinary food will sometimes accomplish the same end. So much for general directions.

WEIGHING FOOD NOT NECESSARY

It may be said in passing that the attempt to have the patient weigh his food does not give the satisfactory results that might be thought. It is more important to educate the diabetic to control his appetite by sheer force of will than it is to induce him to depend on the scale for his food allowance. Few patients will continue to use a scale after they have left the physician's care, while if they have been taught to exercise judgment and self-control in determining the amount of food they may take, a habit will have been formed that will be their salvation.

For drinking, copious draughts of some mildly alkaline water are desirable. The water should have sufficient salts in solution to increase slightly its natural diuretic effect. Distilled water should not be used, at least for any length of time.

The diet should, at first, be restricted as nearly as possible to proteids and fats, unless the patient shows signs of acidosis or impending coma, in which cases carbohydrates must be cautiously given. It is very essential that the food of the diabetic be well cooked, so as to tax to the smallest degree the weak digestive system. As the glucose diminishes, fresh vegetables may be added to the dietary, but of such quantity and kind as not to exceed 4 per cent. carbohydrate. Again it should be stated that the quantity of all food—even if it is carbohydrate-free—must be greatly restricted. The number of calories that the body ordinarily requires is no safe criterion of the amount of food that should be given a diabetic. It is not the quantity of food that should be metabolized, but the amount that can be metabolized, that should determine the amount given to the patient. All in excess of the quantity that the patient can actually use burdens the already overtaxed excretory organs and retards improvement.

OIL IN CONSTIPATION

Olive oil and castor oil, both for the food value and the laxative effect, should be given in all cases in which there is constipation—which means practically all cases. A palatable and efficient emulsion can be made by taking equal parts of olive oil, castor oil and glycerin and emulsifying it with 4 per cent. of Squibb's or Merck's gum arabic.

Castor oil	
Olive oil	
Glycerin āā	320.0
Gum arabic	36.0
Flavoring oil (gaultheria or cassia)	1.0

The patient must have at least one daily bowel movement and should avoid the ordinary purgatives such as aloes, cascara, calomel, etc.

The diabetic should be kept mentally indolent and physically active; at the end of each day he should be tired, but not to the point of fatigue. As much time as possible should be spent in the open air, and the sleeping-room should be as well ventilated as that of a patient suffering from incipient tuberculosis.

GLUTEN FOODS

The question of carbohydrate food is, of course, the paramount problem in the treatment of diabetes. The prescribing of so-called gluten flours has, in the past, been one of the most pernicious errors met by the physician who treats diabetics. In the first place, a very large proportion of the gluten flours on the American market are practically worthless as an antidiabetic food; in the second place, physicians in prescribing these gluten flours are likely to give their diabetic patients the impression that a gluten bread is a safe bread.

Many diabetics are killed yearly in the United States from the excessive ingestion of starches taken in the form of gluten breads. Ordinary wheat flour contains from 70 to 75 per cent. carbohydrates, and most of the widely advertised American brands of gluten flour contain all the way from 43 to 73 per cent. carbohydrate. These flours are not only absolutely worthless for the diabetic, but are exceedingly dangerous, because of the false sense of security which the term "gluten bread" carries with it. A flour containing 40 per cent. of starch may be useful in cases of transient glucosuria, but it has absolutely no place in the treatment of true diabetes. It is but fair to say that there are a few diabetic flours on the American market whose starch content brings them within the limit of safety—provided the quantity eaten is most carefully gauged.

Forced some years ago, by the inability to find a safe flour on the market, to devise a starch-poor bread or biscuit I have long given my patients a bread made after the following formula:

Unground poppy-seed	3 lbs.
Ground nuts (almonds, pecans, English walnuts or filberts; or a combination of these)	8 lbs.
Eggs	12
Flour of dried spinach	1 lb.
Salt	to flavor
Milk	enough to make a stiff batter

This batter, shaped into small biscuits or crackers, is baked and, if needed to be kept for any length of time after baking, is thoroughly dried at a mild heat until the moisture is reduced to 0.25 of 1 per cent. The dried biscuits are kept in hermetically sealed tin cans. Put up in this manner they may be kept indefinitely in perfect condition. These biscuits contain about 5 per cent. of carbohydrate.

The drying of these crackers is desirable because it necessitates the most thorough mastication, and thorough insalivation of food is one of the prime requisites of the successful treatment of diabetes. It is for the purpose of favoring mastication that the poppy-seeds are incorporated, although the oil they contain also increases the caloric value of the biscuit. But thorough chewing of the biscuits brings out the flavor of the poppy-seeds, and the pleasure of eating is much increased. The belief, common among laymen, that poppy-seeds contain opium, is, of course, erroneous. Of course these biscuits, like all other starch-poor products, are not so palatable as ordinary bread or biscuits. But they make a very safe and acceptable substitute for bread, and that is all that can be asked for.

SEVERE CASES

To go back to the patient: If, after two weeks of strict antidiabetic treatment the sugar does not disappear, the patient should be put to bed and placed on a diet consisting of one raw egg and 2 ounces of olive oil, three times or even four times a day, still continuing the free use of mildly alkaline drinking waters. Should the urine show the presence of diacetic acid, the oil must be reduced in quantity and small amounts of carbohydrates given—the patient, meantime, being kept in bed. Sometimes, in cases in which the system is threatened with an overwhelming acidosis, the temporary administration of small quantities of sodium bicarbonate may be tried, although I have seldom seen any good effect from it. This should be given as nearly as possible midway between meals, so as to cause the smallest degree of interference with digestion. As, however, it will cause some digestive disturbance no matter how carefully administered, its administration should not continue for any length of time.

After getting the patient to the point where the urine is sugar-free, small quantities of carbohydrates should be cautiously added to the dietary. Just as the presence of sugar in the blood establishes a vicious circle and causes the system to become still less able to "burn up" the sugar, so the absence of sugar gives the organism a greater tolerance for this necessary food. The carbohydrate should be added gradually, first at one meal only each day, and that meal preferably breakfast, as metabolism seems more active at that time. As systemic tolerance is increased, the starchy foods may be added to other meals until the point is reached where sugar appears in the urine; when this occurs, all starches should be withdrawn for a day or two and then gradually given again to a point just below that which has been shown to be dangerous.

It is better to add the starch in but one form, rather than several, as the system seems better able to adjust itself to one form of carbohydrate than to several, even though the sum total of starch be the same. What form that should be, can only be determined by experiment. Patients seem to differ in their ability to digest various forms of starch. One man may be more tolerant of bread-starch than of potato-starch; another may be unable to assimilate either bread- or potato-starch and may tolerate small quantities of oat-starch. These individual peculiarities must be ascertained and the results heeded. Another thing to be borne in mind is that all foods that are difficult for the patient to digest—whether they are starch-free or not—should be carefully avoided.

CONTROL OF THE PATIENT

Every physician who has treated many diabetic patients knows that, on the subject of eating, the diabetic is mentally unbalanced. This is true, not only regarding carbohydrate-containing foodstuffs, but regarding the quantity of all foods. Most diabetics suffer from an insatiable hunger. Successful treatment, therefore, depends wholly on the degree of control which the physician can exercise over his patient. In many cases the patients need to be watched with as much care as though they were morphin habitués undergoing antinarcotic treatment.

It is impossible to overemphasize the fact that the *quantity of food is as important as the kind of food.* It must be evident that a sick person cannot digest the same amount of food that a well person can, and it is the height of folly to permit the diabetic to eat voraciously, even of foods that are absolutely starch-free.

In the case of children it is practically always essential to put the patient in the charge of a competent disinterested person, such as a nurse. Experience has shown that relatives, especially parents, are utterly unable to withstand the tears and pleadings of the child for the deadly carbohydrates which its system craves and for which its whole being cries out. It is seemingly impossible to bring the layman to a full realization of the fact that the sugars and starches, which in health are harmless and necessary and which form so important a part of his daily dietary, are to the diabetic the most deadly and overwhelming poison. In spite of the usual doleful prognosis given in cases of juvenile diabetes, in cases in which the child can be absolutely controlled, the outlook is by no means so black as it is usually painted. This careful supervision must extend over years of time, as the child's system has to be "rebuilt."

Nor are children the only ones who need careful watching and oversight. One of the essentials to successful treatment is that the physician shall see the patient daily until the disease is well under control. A specimen of urine should be brought each day and an increase in the daily output of sugar calls for a careful inquiry into the dietetic and hygienic incidents of the day before. It should be insisted that the patient write down and bring a list of the kind and amount of food eaten each day. This not only permits of special directions being given regarding certain articles of diet, but it acts as a check on the patient. Many who would not hesitate to vary from the truth when giving a verbal account of the day's dietary will think twice before putting an untruth in writing. Printed diet lists containing general instructions should be given to every patient, while specific written directions should be given to every individual according to his needs.

Diabetes has already been compared to chronic morphinism or alcoholism, and so far as the principles of treatment are concerned the simile is a good one. The personality of the physician is of great importance. The patient must be impressed with the need of obeying instructions. We are creatures of habit and in the diabetic there is usually a vicious dietetic habit to overcome. Without the hearty cooperation of the patient the successful treatment of diabetes is impossible.

A TYPICAL CASE HISTORY

The following case history may be given as fairly typical of the patients that make up the majority of those treated:

Patient.—Swede, aged 40, married, father of five children, a carpenter by trade, consulted Dr. A. J. Ochsner because his hands and feet were cracked and bleeding. Dr. Ochsner after diagnosing the condition as one of diabetes, did not treat the patient but referred him to me for treatment.

History.—He had the disease, to his knowledge, for about 18 months when first seen. He had taken codein and arsenauro in large doses and over a long period; had been permitted to eat all the so-called gluten bread that he wished, and no restriction had been placed on the amount of starch-free foods that he had taken. He had been given a diet slip issued by a proprietary house and permission had been granted to eat any of the foods that the list did not prohibit. Before the diabetic condition developed he had eaten large quantities of partly cooked starches, had bolted his food and had partaken of a badly balanced diet; one containing large amounts of carbohydrate.

Condition When Examined.—The patient was passing from 4 to 5 liters of urine daily of a specific gravity of 1.046. There was no albumin and but occasional casts. The skin on the hands and feet was dried, cracked and bleeding.

Treatment.—Twelve glasses (8-ounce capacity) daily of mildly alkaline water was immediately prescribed. All so-called gluten foods were immediately withdrawn and the starch-poor (5 per cent.) biscuits previously described were substituted. The amount of all food—starch-free and otherwise—was greatly reduced. Castor oil in doses sufficient to overcome the constipation was given, but no other drugs were used. The glycosuria gradually diminished and finally after four weeks entirely disappeared.

Subsequent History.—No return of the glycosuria had occurred up to the time of his death from pneumonia eleven years later, during which period he returned for examination five times at intervals of about two years. During this entire time the patient tested his own urine with urinometer regularly according to instructions that are given during treatment to all adult patients.

SUMMARY

In brief, then, the following points are essential to the successful treatment of diabetes mellitus:

1. To impress on the patient that after his apparent recovery continued care in eating is essential to continued health.
2. To dispense, as a general thing, with such drugs as codein and arsenic and to make the patient rely practically entirely on the diet and hygiene.
3. To insist on the restriction of the quantity of food just as much as of the kind.
4. To overcome constipation by the use of castor oil and olive oil or by the use of a mixture of these two with glycerin.
5. To insist that the food must be thoroughly masticated.
6. To restrict carbohydrates at the outset to the smallest possible amount consistent with safety.
7. To add starches gradually in but one form rather than in several until the point of tolerance has been reached.
8. To eliminate from the dietary those articles of food that have been found to be difficult of digestion, even in health, though their starch-content may not be objectionable for a diabetic.
9. Above all, to impress the patient with the fact that his disease is essentially the result of vicious dietetic habits and that it is useless for him to expect any favorable results so long as the habit is persisted in.

ABSTRACT OF DISCUSSION

DR. ROBERT T. MORRIS, New York: I wish Dr. Hodgson had described post-mortem examination of the pancreas in his report on cases of diabetes. An interstitial pancreatitis, toxic in origin, squeezes out the islands of Langerhans in a proportion of cases of diabetes, and this fundamental cause for some cases of diabetes has been mostly overlooked. Go back of every case of diabetes. Speak of the fundamental causes. Refer to diabetes as a symptom only. You may have to go back to a fibroid appendix, a loose kidney, eye-strain, cholecystitis and the whole chain of factors in the production of toxic influence from the bowel. This toxic influence often induces an interstitial pancreatitis, the islands of Langerhans are squeezed out and diabetes results as a terminal symptom. Anything which irritates the floor of the fourth ventricle of the brain may have diabetes as a terminal symptom. It is not enough to speak of errors of digestion when discussing the subject of diabetes. Go back a step farther and tell us what is causing the errors of digestion. Surgeons have to deal with diabetes only when the hygroscopic sugar in the blood abstracts water from all body cells, and causes surgical conditions, or interferes with repair in surgical conditions of other origin; but we know that physicians as a rule are not going far enough back in their treatment of diabetics. We know they are not going back to the primary causes for the indigestion which leads to the toxemia which injures the pancreas and ends in the symptom known as diabetes. Examine the pancreas post mortem in more cases, and give us reports on unsuspected interstitial pancreatitis.

DR. EDWARD F. WELLS, Chicago: No foundation for the treatment of diabetes can be considered complete until there has been added to the nosologic diagnosis another and broader one, which may with propriety be termed a therapeutic diagnosis. My practice is as follows: The patient, whom we will assume to be somewhat beyond middle age, continues the diet to which he is accustomed for three days, during which time daily examinations are made of the twenty-four hours' urine. He is now placed on a diet from which carbohydrates are closely excluded, and this is continued until daily analyses show absence of urinary sugar, or until it declines to a point below which it will not descend. There is now added to the diet, carbohydrates, as for example, bread, in definite amounts, which are daily increased until sugar reappears, or increases, in the urine. A daily carbohydrate dietary contingent which falls well short of the patient's glycogenic capacity, as above determined, should be his limit in this class of foods. It is interesting to note that in these cases an increasing tolerance is developed by keeping the sugar out of the urine, or by keeping it down to the lowest possible level. Therefore, about twice a year the test is repeated, in order that, should such increased tolerance develop it may be discovered and measured, with a corresponding readjustment of the carbohydrate content of the dietary. Not only does this method permit intelligent management, but it necessitates taking the patient into partnership in the study and management of his case, thereby maintaining his interest through the many years during which the treatment must continue, which is until death ensues. These patients never recover; but if they receive such proper management as may be readily given them, they need not die from, although they will die with, diabetes.

DR. HENRY B. FAVILL, Chicago: I am very much impressed by what Dr. Hodgson says as to his accomplishments in cases of diabetes taken at random, but my own success has been various and not altogether satisfactory. I have no hesitation in subscribing to the detail which he sets forth, but I have not the least expectation of securing in general the percentage of satisfactory results which he can show.

Classification of glycosuria is difficult and at present not authoritative. It is to some extent a matter of words. What is the dividing line between "glycosuria" and "diabetes"? Is there a scientific distinction? Is it a matter of degree or is it a matter of personal equation and judgment? Is it not somewhat a matter of temperament on the part of the physician who classifies? Although I am in substantial accord with what Drs. Morris and Wells have stated, I still am at sea at this classification. In the course of the year I see many cases showing sugar in the urine. I have not called them diabetes, however, unless the sugar has persisted. A case of glycosuria which clears up temporarily and remains clear for a reasonable length of time I do not call diabetes. However, what right have I to say that one is a case of diabetes and the other is not? This brings us really down to the practical question.

The broad handling of glycosuria, in my opinion, is based on a few facts. 1. There is a transitory glycosuria which is very transitory and unquestionably dietetic. 2. There is a glycosuria much more grave and largely amenable to dietetic regulation. 3. There is a glycosuria which is undoubtedly pathologic in its anatomy, which is only slightly amenable to regulation of the diet. This last is fundamentally progressive and the cases are more or less hopeless. I think we can say that we have all sorts of gradations in these questions and the question is not one particularly of a pathologic classification but a matter of judgment—that is to say, the interpretation of the practitioner.

The principles of dietetics have been thoroughly well stated, particularly with regard to limitations in amount and as to bringing the total food down to what the individual can safely handle. There is a matter which has not been mentioned which I think is of importance: the reciprocal balance between the capacities for assimilating carbohydrates and proteins. In a large percentage of patients, particularly those of a full habit, the capacity for handling carbohydrates can be pushed to a higher point by reducing the protein demand on the system. So far as my own observations have gone, individuals with glycosuria or with diabetes, who are well nourished, quite plethoric, respond quickly and favorably to the diminishing of their nitrogenous intake. The benefits from this process as a rule are greater than that from cutting down starches. I wish to emphasize also what Dr. Hodgson has said about cutting down the total food to the point of tolerance without any regard at first to theoretical caloric value.

Dr. R. Wernick, Los Angeles, Cal.: There is one thing I believe to be of importance, that has not been mentioned, pertaining to the administration of alkali by the stomach. In children, I prefer to administer the alkali by way of the bowel. The acid gastric juice stimulates both the liver and pancreas to action; and the administering of large doses of alkali by way of the stomach naturally interferes with the acidity of the stomach contents. I find that by administering alkali by the bowel I get far better results. Of course, in acute cases in which we do not want to stimulate the pancreas, we must administer alkalies by the stomach. Even after the abatement of the condition, it is advisable to give the alkalies by the bowel. Fifteen or twenty years ago, I had a horror when called on to treat a case of diabetes occurring in a child. I am glad to say, however, that in later years I have experienced a change of opinion, and I have been able to save several children. I have among my patients young girls and boys who were suffering five or ten years ago from diabetes. After acute diseases, frequently as a result of infection or inflammation, the islands of Langerhans are involved, and the functions of the pancreas interfered with, and as we often see the hydrochloric acid reappear in an acid stomach after prolonged absence, so also does the pancreas frequently resume its functions after prolonged treatment, unless, of course, the islands of Langerhans are totally destroyed.

Dr. A. J. Ochsner, Chicago: Naturally surgeons get many cases of diabetes; they come to us, or are sent, because of the accompanying gangrene. Twenty years ago we expected after an amputation of a limb because of diabetic gangrene, to have in a large proportion of cases, diabetic coma and death within forty-eight or seventy-two hours. Since that time my opinion has changed. Because of what I have learned from Dr. Hodgson I find that in my diabetic amputation cases the wounds heal by first intention. Dr. Hodgson has had these patients heal by first intention. After Dr. Hodgson has had these patients under observation for three or four weeks one cannot get them to eat anything he has forbidden. He impresses certain ideas on his patients and the patients stand by them. Some of Dr. Hodgson's patients under by observation have followed out his ideas and his directions for as long as sixteen years and have been free of sugar for this entire period of time. He goth these patients to believe that they should not eat four times as much as was necessary to be well; he got them to practice what he taught, and this, I believe, is the secret of his success in handling cases of diabetes.

I have operated on a large number of patients with pancreatitis and I have found a few suffering with diabetes; but this proportion was exceedingly small. Unfortunately, I am not in a position to make autopsies in cases of death of patients with diabetes. The same as most of you, I must go by what I find in the literature concerning the results of pancreatitis, and especially the effects of pancreatitis on the islands of Langerhans. That there is danger from pressure on the islands of Langerhans is undoubtedly true. If the patient does not die, how can we say that there is pressure on the islands of Langerhans as the result of diabetes? If we had a large number of cases coming to us for operation with pancreatitis, suffering also from diabetes, and if we could make autopsies in these cases, this point could be proved. But this is a point that is well worth bearing in mind and following out; in every case of diabetes resulting in death there should be a necropsy. Another thing of importance is to get people to understand that they are not well because of taking this, that or the other medicine; they get the idea that it is this or that medicine that cures them when, in fact, it is the dietetic treatment that results in good.

Dr. A. J. Hodgson, Waukesha, Wis.: Details are necessary, of course, but to give the details of 100 patients suffering from diabetes, especially with regard to the qualitative and quantitative values of the food, would be almost impossible. Such details would fill many books. It should be remembered that every patient must be treated individually. No set rules will apply to all. With regard to the cases of pancreatitis, I am not certain as to the causes of this manifestation of diabetes. I have met with cases of pancreatitis, but I have never yet met with anyone who could inform me as to the causes. When these patients died and were brought to post mortem, the condition was found but it was not diagnosed during life. I think, however, that the long-continued influence of the toxemia, the toxemic poison, is a sufficient cause of the degeneration found, and thus a cause of the pancreatitis. I wish to emphasize the fact that no one can have sugar in the urine for any length of time without having some pathologic changes in the body. One of the symptoms which should be looked for is the loss, or partial loss, of sight; this is not due to cataract but possibly to an anemic condition of the retina caused by the presence of sugar in the blood. Many of these conditions have been mentioned in my paper. I have never seen any benefit result from the giving of strong alkalies that has not been secured by giving large draughts of a mildly alkaline water. I do not believe that the administration of sodium bicarbonate has any value in the curing of this trouble. Give plenty of mildly alkaline water; this is far better, in my opinion, than giving the strong alkalies.

Contribution to Knowledge.—The requirement that the investigator learn what other men have done before him in the field he seeks to enlarge, gives him an unusual realization of the part he may be playing in the promotion of natural knowledge. Knowledge grows like the picture in the dissected puzzle. Every addition must fit the parts already arranged in order to possess significance, and also every addition makes possible the fitting of new parts whose positions in the enlarging picture become thereby suddenly revealed. One of the delights of research, therefore, is the sense that every bit of new knowledge finds its place in the structure of truth, and that sooner or later it will be required for the further building of that structure. The relation which the fresh contribution bears to that already established, the discoverer clearly sees; what relation it will certainly bear to further contributions he may never know. How little did the men who studied the minute differences among mosquitoes, and who recorded the breeding habits of those insects, realize their important rôle in abolishing the pestilence of yellow fever, and in bringing about the immense social and political changes which will result from that conquest!—Cannon in *Science*.

THE DETECTION AND ESTIMATION OF GLUCOSE IN URINE *

STANLEY R. BENEDICT
NEW YORK

A REAGENT FOR QUALITATIVE USE

The property possessed by glucose, in common with many other sugars, of readily taking up oxygen in alkaline solution, is almost universally employed as a means of detecting this substance in urine.

The glucose molecule itself, however, is not the active reducing substance in alkaline solution, it having been previously shown[1] that the reducing action is due to a substance formed from the action of alkali on the sugar molecule. The reducing substance thus formed is not stable toward strong alkali, and unless permitted to exhibit its reducing action at once, is rapidly decomposed into compounds which have no reducing power, if sodium or potassium hydroxid be present. Solutions of the alkali carbonates, on the other hand, form the reducing substance from glucose a little more slowly than do the hydroxids, and have little, if any, destructive action on the reducing substance after it has been formed.

From a consideration of these facts it may be inferred that the presence of the strong alkali in Fehling's fluid may, under certain circumstances, interfere with the power of this solution to demonstrate small quantities of sugar. The urine, for instance, contains compounds (chief among which is probably creatinin, as pointed out by Maclean[2]), which seriously interfere with the detection of glucose by Fehling's solution. Thus, although Fehling's solution will detect 0.001 per cent. of glucose in pure solution, at least a hundred times this amount must be present in urine to give a positive reaction with this reagent. This marked loss in delicacy of Fehling's test when applied to urine is unquestionably due to the fact that the normal reduction of the solution is inhibited for a period long enough to allow the strong alkali present to decompose the reducing substance formed from the sugar molecule. For the most part these facts were pointed out in the communication above referred to,[1] and the advantages of employing a copper solution in which alkalinity is secured by carbonate instead of hydroxid, for the detection of sugar in urine, were also mentioned.

It was shown in this connection that a solution containing copper sulphate, Rochelle salt and sodium carbonate is more than ten times as delicate a test for glucose in urine as is Fehling's solution. Not only is such a reagent delicate for the detection of sugar in urine, but it is also *more specific*, in that it is not reduced by many non-carbohydrate substances which readily reduce copper in the presence of the stronger alkali. Chloroform, chloral, formaldehyd, aldehyd, uric acid and creatinin all reduce Fehling's solution, while they are without appreciable effect on the carbonate reagent.

This reagent, however, as originally proposed, and containing copper sulphate, Rochelle salt and sodium carbonate, has a disadvantage which is common to so many of the alkaline copper solutions, in that, after mixing, it rapidly deteriorates and becomes unfit for delicate work. It has been found, however, that if the Rochelle salt in such a solution be replaced by sodium or potassium citrate, a mixture is obtained which is very sensitive for sugar detection, especially in urine, and may be kept ready-mixed indefinitely without undergoing the slightest change. This solution has the following composition.

	gm. or c.c.
Copper sulphate (pure crystallized)	17.3
Sodium or potassium citrate	173.0
Sodium carbonate (crystallized)[3]	200.0
Distilled water to make	1,000.0

The citrate and carbonate are dissolved together (with the aid of heat) in about 700 c.c. of water. The mixture is then poured (through a filter if necessary) into a larger beaker or casserole. The copper sulphate (which should be dissolved separately in about 100 c.c. of water) is then poured slowly into the first solution, with constant stirring. The mixture is then cooled and diluted to one liter.

This reagent is about ten times as sensitive to sugar in urine as is Fehling's or Haines' solution, and unlike these latter solutions, is not appreciably reduced by creatinin, uric acid, chloroform or the simple aldehyds. The mixture may be kept indefinitely in uncolored glass or cork-stoppered bottles. Samples prepared over two years ago show no detectable change. Although the reagent is very sensitive for detecting sugar in urine, normal urines give no trace of a reaction when tested with it. An examination of hundreds of samples with the solution served to demonstrate that whenever a positive reaction is obtained, pathologic quantities of dextrose are present. Homogentisic acid (from the urine of alkatonurics) or greatly increased amounts of glycuronic acid, both of which substances readily reduce Fehling's solution, will also affect the carbonate-citrate reagent, and when the presence of these substances is suspected, the urine should be tested before and after fermentation with yeast. If the reducing action of the urine is apparent after twenty-four hours' fermentation, the reduction is not due to glucose, but may be due to lactose, or to either of the substances mentioned above. Interference from homogentisic acid is exceedingly rare, and occurs from glycuronic acid only after the ingestion of drugs which lead to increased elimination of this substance.

In regard to the use of the reagent recommended in this paper, it should be pointed out that until one is familiar with its behavior the following directions should be closely adhered to. The solution is unlike Fehling's reagent in many respects, and should not be used in the same way as this latter solution. No strongly dehydrating substance (such as caustic alkali) is present in the new reagent, hence its reduction product is apt to be yellow, or even greenish-yellow (consisting of the hydrated suboxid of copper) rather than the red suboxid. For the detection of glucose in urine about 5 c.c. of the reagent are placed in a test-tube and *8 to 10 drops (not more)*, of the urine to be examined are added. The mixture is then heated to vigorous boiling, kept at this temperature for one or two minutes, and allowed to cool spontaneously. In the presence of glucose *the entire body of the solution will be filled with a precipitate*, which may be red, yellow or greenish in tinge. If the quantity of glucose be low (under 0.3 per cent.) the precipitate forms only on cooling. If no sugar be present the solution either remains perfectly clear, or shows a faint turbidity that is blue in color, and consists of precipitated urates. The chief points to be remembered in the use of the reagent are (1) the *addition of a small quantity of urine* (8 to 10 drops) to 5 c.c. of the reagent, this being desirable not because larger amounts of normal urine would cause reduction of the reagent, but because more delicate results are obtained by this procedure, (2) vigorous boiling of the solution after addition of the urine, and then allowing the mixture to cool spontaneously, and (3) if sugar be present, the solution (either before or after cooling) *will be filled from top to bottom with a precipitate*, so that the mixture becomes opaque. Since bulk, and not color, of the precipitate is made the basis of a positive reaction, the test may be carried out as readily in artificial light as in daylight, even when examining for very small quantities of sugar. The solution is not dark-colored like Fehling's fluid, so that the precipitate may readily be observed without waiting for it to settle.

A RAPID METHOD FOR THE QUANTITATIVE DETERMINATION OF SUGAR IN URINE

By modifying the composition of the solution described above, it has been found possible to apply the reagent to the rapid and accurate estimation of sugar in urine. Like the old titration process of Fehling, the method described below is based on the fact that in alkaline solution a given quantity of glucose reduces a definite amount of copper, thus decolorizing a certain amount of the copper solution. In the new method, however, instead of the reduced copper being precipitated as the red suboxid, which of its own color obscures the end-point of the reaction, the copper is precipitated as cuprous sulphocyanate, a snow-white compound, which is rather an aid than a hindrance to accurate observation of the disappearance of the last trace of blue color. The solution for *quantitative work has the* following composition:

	gm. or c.c.
Copper sulphate (pure crystallized)	18.0
Sodium carbonate (crystallized)[4]	200.0
Sodium or potassium citrate	200.0
Potassium sulphocyanate	125.0
Five per cent. potassium ferrocyanid solution	5.0
Distilled water to make a total volume of	1,000.0

With the aid of heat dissolve the carbonate, citrate and sulphocyanate in enough water to make about 800 c.c. of the mixture, and filter if necessary. Dissolve the copper sulphate separately in about 100 c.c. of water and pour the solution slowly into the other liquid, with constant stirring. Add the ferrocyanid solution, cool and dilute to exactly 1 liter. Of the various constituents, the copper salt only, need be weighed with exactness. Twenty-five c.c. of the reagent are reduced by 50 mg. of glucose.

Sugar estimations are conducted as follows: The urine, 10 c.c. of which should be diluted with water to 100 c.c. (unless the sugar content is believed to be low), is poured into a 50 c.c. burette up to the zero mark. Twenty-five c.c. of the reagent are measured with a pipette into a porcelain evaporation dish (25-30 cm. in diameter). 10 to 20 gm. of crystallized sodium carbonate (or one-half the weight of the anhydrous salt) are added, together with a small quantity of powdered pumice-stone or talcum, and the mixture heated to boiling over a free flame until the carbonate has entirely dissolved. The diluted urine is now run in from the burette, rather rapidly until a chalk-white precipitate forms, and the blue color of the mixture begins to lessen perceptibly, after which the solution from the burette must be run in a few *drops at a time, until the disappearance of the last trace of* blue color, which marks the end-point. The solution must be kept vigorously boiling throughout the entire titration. If the mixture becomes too concentrated during the process, water may be added from time to time to replace the volume lost by evaporation. The calculation of the percentage of sugar in the original sample of urine is very simple. The 25 c.c. of copper solution are reduced by exactly 50 mg. of glucose. Therefore the volume run out of the burette to effect the reduction contained 50 *mg. of the sugar.* When the urine is diluted 1:10, as in the usual titration of diabetic urines, the formula for calculating the per cent. of sugar is the following:

$$\frac{0.050}{X} \times 1{,}000 = \text{per cent. in original sample, wherein } X \text{ is the number of cubic centimeters of the diluted urine required to reduce 25 c.c. of the copper solution.}$$

In the use of this method chloroform must not be present during the titration. If used as a preservative in the urine it may be removed by boiling a sample for a few minutes, and then diluting to its original volume.

Like the reagent for qualitative employment, the one for quantitative work will keep indefinitely after its preparation. As regards the accuracy of the method, it may be stated that repeated determinations, and comparisons with results by the polariscope and by Allihn's gravimetric process have shown the method to be probably more exact than any other titration method available for sugar work.

137 West Fifty-Ninth Street.

DANGERS OF CERTAIN ETHICAL PROPRIETARY PREPARATIONS TO BOTH PHYSICIANS AND PUBLIC*

M. H. FUSSELL, M.D.
PHILADELPHIA

So much has been written on this subject that a new paper may seem superfluous. The reasons which have impelled this paper are the following:

1. My desk is continually flooded with medicaments sent by manufacturing pharmacists, and delivered by detail men who talk quasi-scientifically, and just as glibly as they did when I began to practice twenty-five years ago.
2. In mingling with other physicians I find many such mixtures and new preparations used in practice, the only excuse being the recommendations contained in literature accompanying the preparations.
3. Many such preparations are used by physicians without any knowledge of their contents or action. There can be no doubt that this use of the preparations is attended by dangers which I hope to make plain.
4. With few exceptions the preparations sent about as samples are mixtures. Now, every intelligent physician knows that if our use of drugs is to be of the least value, each prescription used must apply to the case in hand. It is literally impossible to make a cough mixture, a constipation pill, a remedy for nervousness, and so forth, that will be suitable for all cases. To teach that it is possible to do so, is most pernicious. We may as well—and indeed this often comes to pass under such circumstances—tell our patients they have pneumonia and send them to the druggist for a remedy for pneumonia. These dangers are particularly great to young men just entering the practice of medicine.

Numbers of conditions are necessary for intelligent therapeusis. Among them stand preeminently a careful diagnosis, accurate knowledge of the pathology of the condition under treatment; and an intelligent understanding of the action of the remedy to be used and what we expect to gain by its use. I realize that we cannot always make a diagnosis, that we do not always know the pathology of the condition we are forced to treat, and that we frequently use drugs and other remedies symptomatically. Indeed, as we do not know the cause of all diseases, we are in such cases forced to relieve the symptoms and correct the effects of disease and leave the cure to Nature. This is a most necessary and important duty. To allow a patient to suffer, simply because we cannot strike at the cause of the disease, would be folly. But the physician who leaves no stone unturned will find fewer of these conditions present in his work and will gradually learn to search for and treat the cause of diseases where possible.

---

[4] One-half the weight of the anhydrous salt may be used.

* Read in the Section on Pharmacology and Therapeutics of the American Medical Association, at the Sixty-Second Annual Session, held at Los Angeles, June, 1911.

AN INTELLIGENT UNDERSTANDING OF THE ACTION OF THE REMEDY USED

Can this obtain where such mixtures as I quote below are used? As I write this, I have before me no less than thirty samples of simple drugs and mixtures of drugs which have been left on my desk within the past few weeks. Doubtless the same samples and probably many more have been left on the desk of every physician in my neighborhood. Let me analyze a very few of these preparations:

First I take up Neurosine. The label reads:

> NEUROSINE contains: 5% Alcohol, .075 gr. per oz. each. Ext. Henbane and Fl. Ext. Belladonna, .060 gr. per oz. Oil Bitter Almonds. .60 gr. per oz. Fl. Ext. Cannabis Indica.
>
> *Serial No. 299—Guaranteed under the Food and Drugs Act, June 30, 1906*
>
> NEUROSINE.
>
> The most powerful. Anti-Spasmodic
> Neurotic attainable. Anodyne and Hypnotic.
>
> FORMULA:—Each fluid drachm represents 5 grains each of C. P. Bromides of Potassium, Sodium and Ammonium; ⅛ grain Bromide of Zinc, .075 gr. per oz. pure Extracts Belladonna; .60 gr. per oz. Cannabis Indicas; .075 gr. per oz. Henbane; 7 gr. Extract Lupuli; 5 minims fluid Extract Cascara Sagrada with Aromatic Elixirs. Physicians may rely on this formula. (Beware of substitutes.)
>
> DOSE:—Teaspoonful to a tablespoonful in water, three or more times a day, as in your judgment the case may warrant.
>
> INDICATIONS:—Neurasthenia, Epilepsy, Chorea, Convulsions, Neuralgia, Headache, Delirium Tremens, Asthma, Migraine, Spermatorrhea, Whooping Cough, Alcoholism and all convulsive and reflex neuroses . . . Produces natural sleep. Neurosine contains no Opium, Morphine or Chloral. NO DETRIMENTAL AFTER EFFECTS. In female Neurosis combine Dioviburnia 2 parts, Neurosine 1 part.
>
> DIOS CHEMICAL COMPANY, St. Louis, Mo., U. S. A.

The dangers present in this preparation are:

1. There is no absolute surety that the mixture does contain 5 grains of each of the bromids mentioned, or the other ingredients in the amounts given in the formula.

2. If the maximum dose advised is used, the patient would receive 60 grains of the bromids at a dose.

3. A dose of 0.037 gr. of henbane and belladonna extract might be dangerous if prescribed indiscriminately.

4. The physician is tempted to prescribe a mixture with a fixed and unalterable relative dose of various drugs, instead of prescribing as he should, that dose of each ingredient the special patient needs. Nothing leads more quickly to slipshod methods of practice than this use of compound mixtures for a disease named, rather than for a condition existing in a given patient.

5. The remedy is sold by pharmacists under its attractive and suggestive name, thus enabling the laity to dose themselves to the full with powerful if not distinctly dangerous remedies.

Furthermore, the label is misleading. It uses the name henbane instead of hyoscyamus. The physical action of belladonna and hyoscyamus is much the same. Also, the formula begins "Each fluid *drachm* contains . . .," and continues "0.075 gr. of ext. belladonna per *oz.*" This is confusing if not misleading.

> LIQUOR SEDANS
>
> Alcohol, 30 per cent.
>
> Each fluid ounce represents:

Black Haw	60 gr.
Jamaica Dogwood	30 gr.

> Hydrastine, representing 30 minims Fluid Extract Hydrastis. Aromatics.
>
> UTERO-OVARIAN SEDATIVE AND ANODYNE
>
> Used by leading medical practitioners in the treatment of diseases peculiar to women. The prescribed dose may be mixed with a little hot water before administration, to insure its prompt effect.
>
> DOSE.—One-half to one teaspoonful (2 to 4 c.c.).
>
> Guaranteed by Parke, Davis and Company under the Food and Drugs Act, June 30, 1906. Serial No. 6.

This is distinctly a bad label. In the first place, the common name of *Viburnum prunifolium* and *Pescidia* are used, it would seem, better to attract the attention of unthinking physicians and the laity. It is certainly a stretch of imagination and anything but proper to say that the preparation is used by leading medical practitioners. I would like to know their names.

Here the laity are tempted to use something used by "leading physicians." They are led to self-diagnosis and may miss many important conditions, notably carcinoma of the uterus, from which if there is any relief, the help must come early. Indeed, the physician who uses a preparation labeled "Utero-ovarian sedative and anodyne" will almost invariably depend on what the literature tells him rather than make a careful examination and discover if the patient has a serious disease.

> DIOVIBURNIA
>
> FORMULA
>
> Every fl. oz. contains ¾ dr. each of the fl. Extracts:
> *Viburnum prunifolium,*
> *Viburnum opulus,*
> *Dioscorea villosa,*
> *Aletris farinosa,*
> *Helonias dioica,*
> *Mitchella repens,*
> *Caulophyllum thalictroides,*
> *Scutellaria lateriflora.*
>
> Prepared exclusively for physicians' prescriptions.
>
> Dioviburnia contains: 18 per cent. Alcohol.
>
> Guaranteed under the Food and Drugs Act, June 30, 1906. No. 299.
>
> NOTICE
>
> The attention of the medical profession is called to this preparation on account of its unquestioned value as a uterine tonic and anti-spasmodic.
>
> For indications read pamphlet around this bottle.

This is an especially pernicious form of preparation. In the first place, the value of the drugs is extremely problematic. In the second place, there are eight different drugs, and one fluid ounce of the preparation, according to the label, contains ¾ dr. each. The way the label is printed (3—4 dr. each) might easily lead to the thought that each ounce contained 3 drams or 4 drams of each extract.

Here the physician plays into the hands of unknown men and administers to patients drugs of unknown value in impossible doses. The patient is deceived and the doctor hoodwinked. Can the reader conceive of a more pitiable condition of both patient and physician, than where the physician is driven either through ignorance, indolence or cupidity to use such drugs in such a manner?

GERMILETUM.—Alcohol 18 per cent.; Formalin ¾ M. per oz. Amylacetate ⅓ M. per oz. Guaranteed under the Food and Drugs Act, June 30, 1906. Serial No. 299.

GERMILETUM

(Gim)

A perfect Antiseptic Germicide and Deodorant. Slightly Alkaline.

For internal and external use.

UNEXCELLED IN CATARRH AND ECZEMA

Par-Excellent in Obstetrical Practice.

FORMULA.—Borohydrofluoric Acid. Borosalybenzoic Acid, Boroglycerine, Formaldehyde with Menthol, Thymol Amyl Acetate and other Antiseptic Aromatics.

DIOS CHEMICAL CO., St. Louis, Mo.

The formula for Germiletum may safely be called a fake.[1] It is almost criminal to call a mixture like this "par-excellent in obstetrical practice." The dangers are great; there is no certainty, judging from the label, that it is the least value as an antiseptic. To depend on such material is to bring a blush of shame to the school from which we graduated. If there is any one condition which demands rigid antisepsis, it is our obstetrical work.

Let us analyze this "par-excellent" remedy. It contains 18 per cent. of alcohol. Alcohol is certainly valueless in this dilution. Formalin ¾ M. per ounce. I am uncertain what M. represents, possibly a meter. M. is an abbreviation sometimes used for minim. But judging from the odor entirely, there is about as much formalin in the preparations as there is in spring water.

Amylacetate is not mentioned so far as the writer knows in the eighth revision of the Pharmacopeia, and the National Standard Dispensatory (page 168), says: "It is a good solvent for resins, used as a component of fruit essences and as a solvent of resins in the preparation of lacquers and varnishes."

Neither borohydrofluoric acid nor borosalybenzoic acid is indexed in the "Dispensatory."

I repeat that to use such an article as this is to invite the dangers of inaccuracy and omissions.

SYRUP COCILLANA

COMPOUND

Each fluidounce contains:

Alcohol	5 per cent.
Heroin Hydrochlorid	8-24 grains
Tincture Euphorbiapilulifera	120 minims
Syrup wild lettuce	120 minims
Tincture Cocillana	40 minims
Syrup Squill Compound	24 minims
Cascarin (P. D. & Co.)	8 grains
Menthol	6.100 grains

DOSE.—One-half to one fluid-drachm (2 to 4 c.c.).

Guaranteed under the Food and Drugs Act, June 30, 1906.

I have called attention to this preparation before. Is it safe to spread broadcast a preparation that would give 1/24 gr. of heroin to each full dose? No wonder the drug is a good repeater. The laity buys it, the physician prescribes a lot of useless materials and get 1/24 gr. of heroin as the result.

Cocillana, from which the mixture gets its name, is the bark of *Guaria rusbyi,* a tree found in Bolivia. Its action is said to closely resemble that of ipecac. Can anyone suggest a more pernicious method of practicing medicine than using this mixture or any like it for coughs? One thing is certain, to my mind, the man who uses it rarely makes a diagnosis and the firm which sells it helps him in slipshod methods of practice.

ANTIPHLOGISTINE

INDICATIONS

Antiphlogistine can be used in

Pneumonia
Bronchitis
Pleurisy
Osteitis
Periostitis
Sprains
Felons
Sunburn
Metritis
Vaccination Sores
Chronic Ulcer
Swollen glands
Boils
Buboes
Orchitis
External Piles
Moist Eczema
Erysipelas
Frost Bites
Croup
Inflammation of Bowels
Peritonitis
Tonsillitis
Poisoned Wounds
Inflamed Breasts
Bruises
Abscesses
Endometritis
Synovitis
Dysmenorrhœa

And whatever inflammation or congestion is a factor and local treatment is indicated.

Antiphlogistine is a notorious clay preparation. Notwithstanding the Pharmacopeia has added a preparation, cataplasma kaolini, which is said to resemble closely this preparation, it is little less than dangerous for the patient to use it in this line of ailments. Think of trifling with it in croup and peritonitis, to say nothing of pneumonia!

Croup should be held up to the laity as quite possible diphtheria. To persuade the parents of a child to apply clay to the throat is in the first place to do no good, and in the second place to invite danger, both to the individual suffering and to the family, for fear of diphtheria.

Pneumonia needs prompt treatment by rest and fresh air, not by clay.

Osteitis brings terrible results in its train. A physician knowing a patient to have osteitis and applying any clay preparation is recreant to his charge.

In regard to peritonitis, what has surgery taught us? That peritonitis has a cause: that this cause must be removed surgically, if our patient is not to risk his life.

ALKALOL

0.05 per cent. Alcohol

Is agreeable, non-toxic, non-irritant: combines correct alkalinity with a mild sedative and astringent action. Gives best results when used from one-half to full strength and frequently applied; particularly adapted to treating acute or chronic conditions in nose, throat, eye and ear. Cleansing and soothing when applied to any irritated or inflamed surface. A refreshing mouth and tooth wash in illness and health. In nasal or pharyngeal catarrh, hay fever, asthma, acute cold in the head, follicular tonsillitis, diphtheria or scarlet fever, it will keep nose and throat clean and add much to the patient's comfort. For burns, bruises, insect bites, ulcers, or any local inflammation, constant application by means of saturated gauze or cotton is desirable. Internally, Alkalol may be given in teaspoonful or tablespoonful doses.

Original Package, 8 oz., 50 cents; 16 oz., 75 cents.

ALKALOL CO., Taunton, Mass., U. S. A.

This is a famous alkaline wash; certainly no better, where it is useful at all, than normal salt solution and useless in asthma and diphtheria.

And so I might go on through my whole list of thirty samples. Indeed, I might go further as I have done in another article and beseech you to avoid using the compound remedies found in the Pharmacopeia. They all have the common fault of ready-made prescriptions. They are "one-sized suits for a mass of men" and further, many of them are mere copies of well-known patented formulas.

---

[1] 1. Reports of Chem. Lab. Am. Med. Assn., iii, p. 11.

Why are such preparations used? Because we as physicians do not take pains for the best and because by our use of a drug firm's compound, we make it possible for them to sell. Do we not know that every time we prescribe a firm's special mixture, we make it possible for a patient to drug himself both to our loss and to his detriment? Since this article was written, indeed after I had started on my journey west, President Taft, in a most forceful message to Congress, has this to say about patented nostrums and the Food and Drugs Act:

> The Supreme Court has held in a recent decision (United States vs. O. A. Johnson, opinion May 29, 1911) that the Food and Drugs Act does not cover the knowingly false labeling of nostrums as to curative effect or physiological action and that inquiry under this salutary statute does not by its terms extend in any case to the inefficacy of medicines to work the cures claimed for them on the labels.
>
> It follows that, without fear of punishment under the law, unscrupulous persons, knowing the medicines to have no curative or remedial value for the diseases for which they indicate them, may ship, in interstate commerce, medicine composed of substances possessing any slight physiologic action and labeled as cures for diseases which, in the present state of science, are recognized as incurable.
>
> An evil which menaces the general health of the people strikes at the life of the nation. In my opinion, the sale of dangerously adulterated drugs or the sale of drugs under knowingly false claims as to their effect in disease, constitutes such an evil and warrants me in calling the matter to the attention of the Congress.
>
> Fraudulent misrepresentations of the curative value of nostrums not only operate to delude purchasers, but are a distinct menace to the public health. There are none so credulous as sufferers from disease. The need is urgent for legislation which will prevent the raising of false hopes of speedy cures of serious ailments by misstatements of fact as to worthless mixtures on which the sick will rely while their diseases progress unchecked.
>
> At the time the Food and Drugs Act was passed, there were current in commerce literally thousands of dangerous frauds labeled as cures for consumption and all lung diseases, cures for all kidney, liver and malarial troubles, cures for diabetes, cures for tumor and cancer, cures for all forms of heart disease in fact, cures for all the ills known at the present day.
>
> Unfortunately the statements were not true. The shameful fact is that those who deal in such preparations know they are deceiving credulous and ignorant unfortunates who suffer from some of the gravest ills to which the flesh of this day is subject. No physician of standing in his profession, no matter to what school of medicine he may belong, entertains the slightest idea that any of these preparations will work the wonders promised on the labels.

I might add to President Taft's sentence: "There are none so credulous as sufferers from disease," or physicians whose libraries are filled with circulars issued by drug firms. I believe that every physician in the United States, indeed every physician in the world, will agree with what President Taft has said so well. His words, I believe, must carry home to every one of my readers the points I wish to make. We, as physicians, have no right to prescribe for a patient anything but that which we know is for his greatest good. We can never fulfil this necessity by using such preparations as I have mentioned. It makes no difference whether the firm is unknown or whether it has a great name. I believe that we are perilously near being worthy of Taft's criticism of using preparations of which the statements are not true when we prescribe in such a manner, and I believe that firms who wheedle uneducated or young and inexperienced physicians into using such preparations are as guilty as the dispenser of a nostrum which he knows to be valueless.

ABSTRACT OF DISCUSSION

DR. THEODORE G. DAVIS, Los Angeles: I believe with Professor Schneider that the reason medical men of to-day use these proprietary preparations is that they know nothing about medicine, for they have not been taught medicine. They know nothing about the drugs they use. All they practically care for appears to be the dose. You cannot get the younger medical students of to-day to study pharmacology and therapeutics. I have taught students in materia medica therapeutics and clinical medicine and can speak from personal experience. The young men of to-day, especially in the state of California (I know it to be absolutely true) pay little or no attention to these subjects because they are not examined in therapeutics and materia medica. Four out of eleven students who were denied a passing mark in an examination that I gave were, without any consideration as to what their ratings were in my examination, passed in materia medica and therapeutics. The only way, I think, is to take the first year in pharmacy, as Professor Schneider has outlined, and let them know the drugs they are to use. They do not know one drug from another. Indeed, I became absolutely disheartened and disgusted in endeavoring to teach, and resigned from the position. It is true not only in California, but elsewhere. The young men of to-day do not study medicine and do not know how to treat the symptoms of disease. They have been taught anatomy, surgery, pathology, bacteriology and diagnosis, yet, as I have said to my classes, "What difference does it make to your patients whether you make a diagnosis or not if you cannot relieve them? If you do not know what to use, except some surgical procedure, what good does it do your patients?" A therapeutic diagnosis should be made with as great care as a pathologic diagnosis. I think that point of view is the point of view from which medical schools should take up the question.

DR. F. E. STEWART, Philadelphia: Dr. Fussell's paper deals with problems of great importance to the profession of pharmacy as well as to the profession of medicine. The term "ethical" as applied to monopolized materia medica products seems to me a misnomer. I can see nothing ethical in the so-called proprietary medicine business. The principle on which medicine and pharmaceal practice is based is altruism. True pharmacy is a branch of medicine and its practitioners are under the same ethical obligations to the profession and to the public as physicians. There can be no two codes of ethics, one for the physician and another for the pharmacist and manufacturer of materia medica products. The dangers referred to by Dr. Fussell would all disappear if both professions would live up to their ethical obligations.

MR. LIGHTHEART, Sacramento: I have had various experiences with various physicians and I can answer in a way some of the questions that have been brought up. I see these things from a different point of view altogether. I am known as an ethical crank. I do no counter-prescribing because I think it is criminal. It is not allowed to go on in my business, but we have physicians who, for instance, advertise listerine. Who started that kind of a proposition? No one but the physicians. The same is true of other preparations. It is only a few years since we had a counter-trade on liquor antisepticus alkalinus. Who but the physician started the laity, by handing it out to his patient? Do not blame the pharmacist for all of these things; he is only too glad to put up prescriptions. I do not want to sell a "patent medicine." I try to persuade people to go to physicians. What do I get? I persuade John Smith to go to a physician; that physician sends that patient to his favorite druggist. I not only lose what little I would make on this particular transaction, but I lose all his patronage. This is a broad question. There is just as much wrong done on the side of physicians as on that of the pharmacists. It has been stated that the average physician does not know how to write a prescription. It was only the other day that I received a prescription containing strontium bromid and aromatic spirits of ammonia. A little while before I had one containing strychnin and strontium—therapeutically and chemically incompatible. I wish that physicians would come to us and say, "Here, can I write such a prescription?" They do it with me. They ring me up on the telephone. I do not see that it belittles the physician to ask the pharmacist. If we come together as scientific and broad-minded men we will accomplish what we desire. Otherwise we will never get anywhere.

DR. M. H. FUSSELL, Philadelphia: I do not know how we are going to get the men who are prescribing these things to cease unless we hold up to their eyes the foolishness of such things. I know that unquestionably the best thing to do is to get the boy before he gets out of college, and that is what we are trying to do. Some years ago in Boston I read an article, for which I was belabored for about a year, on dispensing versus prescribing. I took the ground that it was the duty of the man who lived in a city where he had competent pharmacists to prescribe and not to dispense. In my own particular neighborhood, which is one of the outlying wards of Philadelphia, twenty-four of the twenty-seven physicians living and practicing there do their own dispensing. Now that, I think, is not right. Possibly it was not of any use for me to read my paper, but I am going to continue to write and speak on these lines.

THERAPEUTICS OF ABNORMAL HEART RHYTHM

MAXIMILIAN SCHULMAN, M.D.
Instructor in Therapeutics, College of Physicians and Surgeons, Columbia University; Chief of Clinic in Applied Therapeutics, Vanderbilt Clinic
NEW YORK

A clear understanding of the manner in which disturbances of the cardiac rhythm are produced, and of the meaning of such disturbances, is so important to their intelligent management that I feel justified in presenting this subject, though I have nothing original or new to offer. While this subject has received the attention of many physiologists and clinicians, it is still a mystery to a large proportion of general practitioners, some of those we much respect not hesitating to admit that they "know nothing about it." This apathy cannot be too soon dispelled and it is therefore imperative that practitioners of medicine have this subject so frequently brought to their notice that they will be compelled to study it.

Whether we are ready to admit the correctness of the myogenic theory of cardiac action or not, it must be admitted that studies conducted with this theory as a basis have led to a much clearer understanding of cardiac function, and made possible an analysis of disturbances of cardiac rhythm, which in turn has made treatment of them less empiric than formerly was the case. Just as the recognition of a heart murmur is to some men, even to-day, an indication for treatment of that heart, no matter how well it may be acting, so, to very many more, is the appearance of a disturbance of rhythm a cause for anxiety and the issuing of a bad prognosis, followed by superfluous treatment, medicinal and other.

Incorporated in the adult heart is some tissue which is recognized as the remains of the primitive cardiac tube, and which is of great importance in the functioning of the heart. Modifications of this tissue lead to modifications of the normal functions. Normally, the *most irritable part of this tissue is that situated at the* mouth of the superior vena cava, called the sinoauricular node (Keith; Flack). Here the cardiac contraction is started and the contraction wave is then passed along to the rest of the heart. This node is therefore called the "pace-maker" of the heart's action. Some fibers of the primitive cardiac tissue are probably also scattered throughout the auricular wall, but, because not gathered in any bundles or masses, are harder to recognize. The normal cardiac rhythm, started at the sinoauricular node, is known as the fundamental or sinus rhythm. The rest of the primitive cardiac tissue arises in the auriculoventricular node (Tawara) situated in the wall of the right auricle, near the mouth of the coronary sinus, passes as the auriculoventricular bundle (Kent; His) to the auriculoventricular septum, where it divides into two limbs, one passing down the right ventricle and the other down the left ventricle. The function of this auriculoventricular tissue is to convey the contraction stimulus from auricle to ventricle.

The cardiac muscle is possessed of the following functions:

1. The power to produce a stimulus which will excite the heart to contract: *stimulus production.*
2. The power to receive a stimulus: *excitability.*
3. The power to convey a stimulus from one part of the heart to another: *conductivity.*
4. The power to contract on being stimulated: *contractility.*
5. The power to remain to a certain degree in contraction, even when the active stimulation has ceased: *tonicity.*

A disturbance of these functions leads to a disturbance of the normal heart action. There may be a disturbance of one of these functions without any interference with the others, or, there may be a disturbance of more than one function at the same time.

Heart muscle has a quality peculiar to itself, in that, given a heart which is possessed of excitability and contractility, any stimulus being applied, which is of sufficient strength to cause a contraction, the heart will contract with all its force. The strength of contraction will in no measure be dependent on the strength of the stimulus. Heart muscle either contracts with all the power it possesses or does not contract at all. This is known as the "all or nothing" law. Contracting with all its power, the heart muscle exhausts all its stored energy and as a consequence it becomes incapable of responding to further stimulation until it has had sufficient rest to allow a certain amount of energy to be reaccumulated. This period of non-excitability is known as the "refractory period." A stimulus applied to the heart during a refractory period, will not effect a contraction. It follows *as a corollary that heart muscle cannot be tetanized.* The bearing of these facts on our subject will later be apparent.

The disturbances of rhythm in relation to the several cardiac functions are shown in the accompanying table:

TABLE SHOWING DISTURBANCES OF RHYTHM IN RELATION TO THE SEVERAL CARDIAC FUNCTIONS

Normal cardiac function	Resulting abnormality, when corresponding function is disturbed	
1. Stimulus production.	Sinus irregularity.	Youthful irregularity.
2. Excitability.	Extrasystole.	Auricular. Ventricular. Auriculoventricular.
3. Conductivity.	Heart-block (partial or complete)	Sino-auricular. Interventricular (hemisystole). Auriculoventricular (functional). (organic).
4. Contractility.	Pulsus alternans.	
5. Tonicity.	Absolute irregularity. Pulsus irregularis perpetuus. (Auricular fibrillation, Nodal rhythm).	

The analysis of abnormal cardiac rhythm into the various types, as shown in the table is much facilitated by a study of the venous pulse. This pulse reflects the variations of pressure within the right auricle, and when studied in conjunction with the arterial pulse (and apex-beat) which is the index of pressure in the left ventricle, we are enabled to compare the events occurring in auricle and ventricle at the same moment, and to determine by a comparison with what are known to be the normal relations, the existence or non-existence of disturbances in the case under investigation. For the study of the venous pulse, the internal or external jugular vein on the right side of the neck is usually chosen. The undulations in the veins are the result of the difference in pressure of blood within the veins and pressure of the atmosphere without the veins. When the pressure within is greater than the atmospheric pressure, the vein expands, and when the pressures are reversed, the vein collapses. The normal venous pulse depends on the suction-pump action of the heart. The normal relations of pressure in ventricle, artery and vein, as expressed in graphic curves, are shown in Figure 2.

While the curve obtained from the ventricle, and that from the artery (carotid, brachial or radial, according to special choice, or depending on the apparatus used for taking the tracings) are quite simple and easily understood; that obtained from the jugular is more complicated, and it may be well to here analyze the significance of the crests and vales. The essential crests are those marked *A* and *V;* the essential vales are those marked *X* and *Y.* While the crest marked *C* is of great importance in the analyses of combined tracings, it does not essentially belong to the jugular pulsation, because it is probably not dependent on increased auricular (and venous) pressure, but is transmitted from the carotid artery.

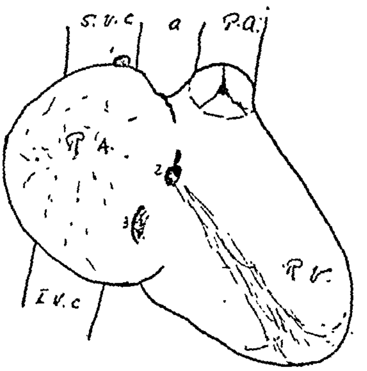

Fig. 1.—Diagram of right side of the heart. *S. V. C.*, Superior vena cava; *I. V. C.*, inferior vena cava; *A.*, aorta; *P. A.*, pulmonary artery; *R. A.*, right auricle; *R. V.*, right ventricle. 1. Sino-auricular node (Keith; Flack). 2. Auriculoventricular node (Tawara). 3. Mouth of coronary sinus. Arising from the auriculoventricular node is the auriculoventricular bundle (His Jr; Kent); which divides in two limbs, one for right and the other for left ventricle.

The crest *A* indicates a rise in auricular pressure due to the systole of the auricle. After this, the auricular pressure falls, to the point *X* (following the broken line) because of several factors; (1) the auricle relaxes after its systole; (2) the auriculoventricular valves are now closed, the ventricle is in systole, and, by virtue of its systolic contraction, it drags down the auriculoventricular septum, so enlarging the auricular cavity; (3) during ventricular systole, the heart becomes smaller in size and also blood is squeezed from the thoracic cavity into the greater circulatory tree, so increasing the negative pressure in the thorax; (4) also, at each systole, the movement of the heart in the chest pulls on the venæ cavæ, and so pumps blood from them into the auricle. While this last does not reduce auricular pressure, it does reduce pressure in the jugular vein. The crest *V*, which follows (ventricular wave; diastolic wave; telesystolic wave) indicates a rise in auricular pressure due to a storing of blood during auricular diastole and ventricular systole. This is followed by a sharp fall in pressure indicated at *Y*, this fall being due to the opening of the auriculoventricular valves which allows the blood stored in the auricle to flow freely into the ventricle. Crest *H* is of less importance, and is sometimes found during the diastolic period, in slowly acting hearts, and supposed to be due to a momentary floating up of the auriculoventricular cusps with the first rush of blood into the ventricle. This sends a wavelet back through auricle into vein. A third heart sound is described as accompanying this wave. Crest *C* is extremely important for clinical purposes. It marks the time of ventricular contraction, and so allows of measuring the time that elapses between auricular contraction, *A*, and ventricular contraction, *C*, i. e., the conduction time. It is of little clinical importance whether Mackenzie is correct in assuming this to be due to transmission of carotid pulsation, or whether it is due to a pushing up of the tricuspid valve when the intraventricular pressure rises during its systole. In either case, it marks the time of commencing ventricular systole and that is the important matter.

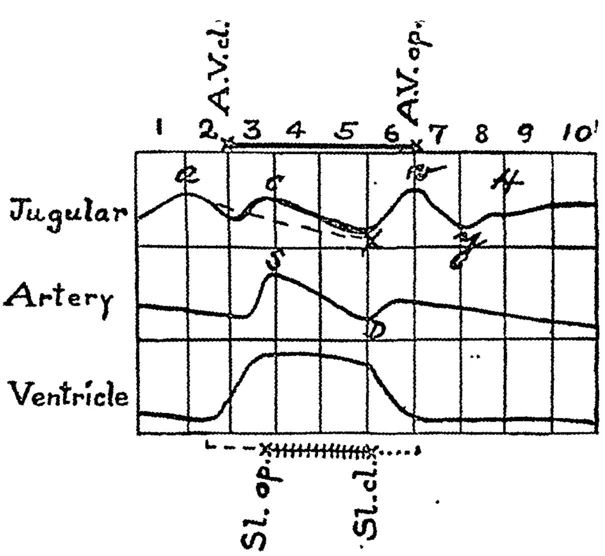

Fig. 2.—Normal relations of pressure in ventricle, artery and vein graphically represented. *A-V. cl.*, Auriculoventricular valves close; *A-V. op.*, Auriculoventricular valves open. In the interval they are closed; represented by a solid line. *Sl. op.*, Semilunar valves open; *Sl. cl.*, Semilunar valves closed. In the interval they are open; represented by a solid line with cross marks (sphygmic period); line of dashes, presphygmic period; line of dots, postsphygmic period. Time 1/10 second. (After Hirschfelder, modified.)

While the above assumes a study of the venous pulse from graphic tracings, and for accuracy these are indispensable, nevertheless the pulse is apparent to the eye, and can be seen in the veins of the neck, as a double wave. This normal venous pulse is called the double, or physiologic, or negative pulse. A venous pulse is obtainable in 80 per cent. of healthy individuals when they are lying down and the neck muscles are relaxed.

SINUS, OR YOUTHFUL IRREGULARITY (DISTURBANCE OF STIMULUS PRODUCTION).

When a normal individual takes some forced inspirations and the pulse is observed, it will be found that it becomes accelerated during inspiration, and slowed during the following expiration and pause. A pulse tracing taken from an artery will show that while the height of the pulse-waves is equal, indicating that the force of the pulse does not vary, the distance between the systolic peaks varies, indicating a variation in length of diastole. Thus, the acceleration and slowing of the pulse are at the expense of diastole. A venous tracing taken at the same time is found to be also perfectly normal except in length of intervals between pulsations, thus corresponding perfectly to the arterial pulse. When such variations appear during quiet unforced breathing, they are abnormal and constitute the sinus irregularity. This irregularity is best marked when the *heart beats slowly, for when it beats fast, the diastolic* period is shortened and hence variations in its length become less apparent. The pathologic physiology of this disturbance is a reflex, acting through the vagus nerve, its inhibitions coming to the sino-auricular node at varying rate. There is here no disease of the heart itself: the cause of trouble lies outside of the heart. One-half hour after 1/60 gr. atropine sulphate is given hypodermatically, a sinus irregularity will usually disappear.

It occurs in young individuals, neurasthenics, and convalescents from acute infectious diseases, such as influenza, etc. It usually gives rise to no subjective *symptoms.* Sometimes the patient is conscious of the irregularity. At times, the period of lengthened diastole may be so drawn out as to cause transient cerebral anemia, with syncope. It is extremely important to recognize this type of irregularity for the *prognosis* is good, even when accompanied by occasional syncope.

Treatment is usually best omitted, so far as the irregularity itself is concerned. If the underlying cause is of sufficient gravity, that should be treated. If the patient does not know of the existence of the irregularity, he should not be told, for the anxiety thus created will make it much worse, and the worry will do the patient more harm than will the sinus irregularity. The patient's family should be made acquainted with the state of affairs, for someone else may discover the irregularity and not recognizing the benign quality of it, start up trouble for the patient, family and previous physician. If any treatment is given at all, it should consist of reassurance, hygiene and nerve tonics. Probably the best drug is sodium glycerophosphate, gr. v, t. i. d. If there is anemia from the preexisting febrile disease, much fresh air, good eggs, and plenty of them, and iron in some form may be prescribed. Sexual irregularities and excesses must be tactfully inquired into and, if found, firmly suppressed.

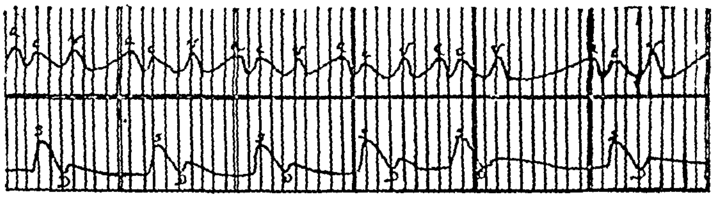

Fig. 3.—Sinus irregularity. Note height of systolic waves—*S*—is equal throughout, but distance between them varies. The venous pulse corresponds to the arterial.

EXTRASYSTOLE (DISTURBANCE OF EXCITABILITY)

While the cardiac contraction wave is normally initiated at the sino-auricular node, any other part of the remains of the primitive cardiac tissue which is found persisting in the adult heart, when rendered sufficiently irritable, may also start a contraction wave. Thus, while the sinus rhythm continues, there may be added to the contractions resulting from this, extrasystoles, due to a heightened irritability of the remaining primitive cardiac tissue. It is to be borne in mind that extrasystoles do not upset the fundamental sinus rhythm, but are interpolated, premature contractions, the impulse for them starting at some abnormal point in the heart. Depending on where these impulses start, we have (1) auricular extrasystoles, the impulse being started in the remains of primitive tissue in the auricle; (2) ventricular extrasystoles when the impulse starts in this tissue found persisting in the auriculoventricular *bundle beyond the auriculoventricular node*, or its ramifications in the ventricle, and (3) auriculoventricular (or nodal) extrasystoles, when the impulse is started in the auriculoventricular node. The several forms may be differentiated by means of polygraphic tracings (Figs. 4 and 5). (Auriculoventricular extrasystole is characterized by a shortened *a-c* interval. Beyond this I shall not discuss it.)

With the beginning of diastole, the heart muscle rests and the energy for its various functions, which during systole is exhausted, is gradually restored. Thus the refractory period of the heart terminates with the termination of systole, and the longer the heart has been in diastole, the more thoroughly are its functions recuperated and the more sensitive is it to stimuli that reach it. When conditions for starting extrasystolic stimuli are present, such a stimulus acting on the heart during diastole, even though premature, will elicit a response and contraction. It is clear that the earlier in diastole this stimulus acts, the feebler the resulting contraction and *vice versa*. Since extrasystoles are always premature, no extrasystolic contraction is as strong as a contraction which results from a stimulus started at the normal time in the cardiac cycle, when the heart's *diastole* is complete and its functional energy completely restored. Extrasystolic contractions sometimes are so premature and so weak as to be too feeble to cause the propagation of a pulse-wave to the wrist, so that it may seem, even on a sphygmographic tracing, that a heart's beat is entirely omitted, because the next normal sinus *stimulus finds the heart in contraction* as a result of the extrasystolic stimulus, hence refractory, and hence does not succeed in causing the contraction at the normal time. This is the *compensatory pause* which follows an extrasystolic contraction, and the time occupied by normal systole + extrasystole + compensatory pause, is equivalent to the time occupied by two complete normal cardiac cycles. The long pause gives the heart a longer rest than it gets during a normal diastole, as a consequence of which it responds to the next stimulus coming from the sinus with more than normal vigor, causing an abnormally large systolic wave in the pulse. A very early and feeble extrasystole which causes no wave in the arterial pulse may be recognized in a tracing from the cardiac apex, and usually also by the heart sounds. If the normal cardiac sounds may be represented as 1-2—1-2—1-2, etc., in case of extrasystole they are 1-2-3-4———1-2—1-2, etc., or, when a very feeble extrasystole, 1-2-3————1-2—1-2, etc. Also 3-4 are feebler than 1-2.

Extrasystoles may appear at regular or irregular intervals, and with varying frequency. They cause one form of pulsus bigeminus, when appearing after every other normal systole.

Extrasystoles point to a heightened irritability of the heart *(disturbance of excitability)* and this usually depends on disease of the cardiac tissue. There may be disease of the myocardium, or, more commonly, of the remains of the primitive cardiac tissue. It is found in hearts the seat of rheumatic trouble and in cardiosclerosis cases, with disease of the coronaries. It is met with in young adults, middle-aged and elderly. While some disease of the cardiac tissue is an underlying condition, functional disturbances that raise the irritability of the entire nervous system often precipitate the appearance of extrasystoles and the removal of such disturbances terminates the attack. This is especially true when it appears in rapidly acting hearts. More commonly, extrasystoles appear in slow-acting sclerotic hearts. Dyspepsia, flatulence, and indicanuria are exciting causes, as also, and quite markedly, the abuse of tobacco.

Symptoms often are absent and this, as a sinus irregularity, may be discovered by accident in the course of a routine examination. When subjective symptoms are noted, it is usually in the younger and neurotic individuals. They complain of "palpitation," and this means, either that they feel the irregular heart action, or that they notice the long pause and apparent stopping of the heart, or, what is more annoying, they feel the "thump" following the long pause and dependent on the abnormally vigorous systole occurring at such time. Rarely, the pause is so long as to cause transient cerebral anemia and syncope.

Prognosis depends on the underlying cause of the trouble. The appearance of the extrasystole in itself adds no great gravity to the condition. The recognition of an extrasystole may, however, be the first thing to attract attention to the heart at all, and a person with extrasystoles is not so good a physical risk as a normal person. Some maintain that it always points to disease of the myocardium. Also, a nervous woman may be made more nervous by the symptoms the extrasystoles cause her, and especially, by the fear of serious heart trouble which they will arouse in her. This increased nervous irritability will, in turn, aggravate the irregularity.

Treatment, again, depends on the underlying cause, and that should be treated. The condition must not be made too much of and the patient must be quieted, not excited and frightened. Worry and sleeplessness must be combated, and a run-down nervous system toned up by hygienic and hydrotherapeutic methods. Dyspepsia must be corrected, and especially should constipation and indicanuria be relieved. For the latter, as a symptomatic remedy, betanaphthol in 3 to 4 gr. doses given in capsules, three times a day, after meals, is very useful. Tobacco should be at first entirely stopped, and when symptoms have disappeared, allowed in very limited quantity. This alone frequently causes a disappearance of gastric hypersecretion and hyperacidity, which are also aggravating factors of the irregularity. As for direct drug treatment, the most important thing to remember is that digitalis, certainly in doses large enough to be of any value in a heart disturbance when it *is* indicated, should in this condition be cautiously avoided. When a heart is irregular and the circulation is so disturbed as to indicate the desirability of digitalis, the irregularity will be found to be of a different type than uncomplicated extrasystole. To small "tonic" doses, such as ¼ gr. of the powdered leaves, three or four times a day, there is no objection, and the same holds good for doses of gr. 1/200 to gr. 1/120 of strychnin sulphate, but the latter also is not to be used in larger doses. Large doses of digitalis may superadd functional heart-block to the extrasystole, for the two are not infrequently combined. Bromids and potassium iodid, the former in 20 gr. doses, t. i. d., and the latter in 5 to 10 gr. doses, t. i. d., are the most commonly useful drugs.

HEART-BLOCK (DISTURBANCE OF CONDUCTIVITY)

The normal impulse for cardiac action beginning at the sino-auricular node, may, in the progress to the rest of the heart, be partly or completely interrupted, thus resulting in partial or complete heart-block. Depending on the point where the interruption occurs, the block is classified as sino-auricular, interventricular and auriculoventricular. The commonest and by far the most important of these, at least for clinical purposes, is the last, and I shall therefore dismiss the other two forms without discussion, except to mention that it is still questionable whether interventricular block (or hemisystole) occurs at all.

Auriculoventricular heart-block may be functional or organic. Functional block is dependent on overstimulation of the vagus nerve, and while a tumor pressing on the nerve and some other still less frequent factors may produce it, the clinical factor of great importance is digitalis poisoning. Organic block is due to disease of the auriculoventricular bundle, depending on old rheumatic infiltration, sclerosis and consequent narrowing of the bundle, or, more commonly, sclerosis secondary to loss of nutrition dependent on fibrosis or sclerosis of the coronary arteries. Rarely, tertiary syphilis (gumma) may be the cause. Auriculoventricular heart-block is therefore found in middle-aged and elderly individuals, those suffering from general arteriofibrosis particularly, and in younger individuals with mitral stenosis.

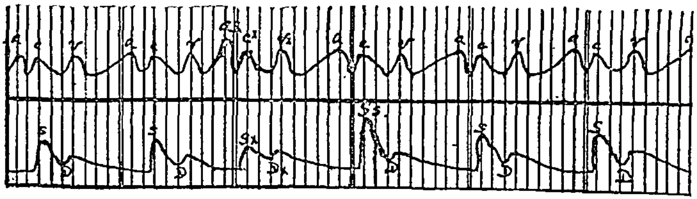

Fig. 4.—Auricular extrasystole. Note the premature auricular contraction at *Ax*, followed by a premaure ventricular systole at *Sx*, which reflects the waves *Cx* and *Vx* in the venous pulse. Note the long pause, with following large systolic wave at *Ss*. Note persistence of sinus rhythm.

On referring back to the diagram of a normal venous pulse-tracing (Fig. 2) in which the pulse is taken as beating at a normal rate (here for the purposes of greater clearness made 60 per minute) it is found that the *a-c* interval is 2/10 second. This *a-c* period is occupied by three events; (1) the auricular systole, (2) conduction of impulse from auricle to ventricle, and (3) the presphygmic period. Event 2 occupies most of this time, and is the only one that is to any degree variable. Therefore any variation in the length of the *a-c* interval, may be ascribed to variations in the rate of conduction, and factors 1 and 3 entirely ignored. A lengthening of the *a-c* interval beyond the normal is the mildest degree of block, and may for a long time be the only objective evidence of trouble. When more advanced, ventricular systoles are at intervals entirely dropped, due to the occasional failure of the impulse to pass over the bundle to the ventricle. Such dropping may occur with varying frequency at irregular or regular intervals and is preceded by a progressive lengthening of the *a-c* interval. Partial block may be so far advanced as to show a single ventricular systole to 2, 3, 4, and even more auricular systoles. When the block is complete, the auricular impulse is not conveyed to the ventricle at all, and the latter chamber assumes an independent rhythm, which is usually 30 per minute, or less. In such case, the radial pulse, while slow, has a regular rhythm, and combined tracings show no regular relation between auricular and ventricular systoles (between *a* and *c* waves of the venous pulse).

In diagnosing heart-block, the type of irregularity most likely to be confusing is extrasystole. While in the latter during the period when a pulse-beat is apparently dropped, the short extrasystolic sounds can be heard, in heart-block, no sound is audible. When polygraphic tracings are taken, the difference is quite readily made out (Figs. 4, 5 and 6).

The subjective *symptoms* vary in intensity with the degree of trouble. The especially characteristic ones, in advanced cases, are those of the Adams-Stokes syndrome; i. e., vertigo, syncope, and epileptiform attacks, with a very slow and intermittent (or regular) arterial pulse. The slow pulse is what most readily raises the suspicion that this condition may exist. In the milder cases the patients suffer symptoms dependent on the insufficient peripheral circulation, for the total cardiac output is necessarily reduced by excessive slowing of the pulse, with its resultant prolongation of diastole into a stage of diastasis.

Prognosis is not good, even in moderate cases, because, when organic the condition, except in the rare cases of tertiary syphilis, is not removable.

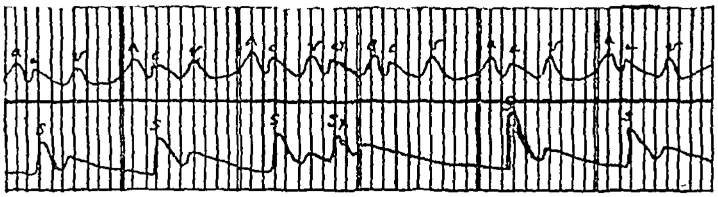

Fig. 5.—Ventricular extrasystole. Note premature systolic wave *Sx*, with reflected *Cx* in venous pulse. Note absence of a premature *a* wave in the venous pulse. Note persistence of sinus rhythm.

Treatment consists in advising the patient to live a life that will require activity only commensurate with a reduced cardiac output. If subject to syncopal attacks, he must be cautioned against being about alone, particularly in places where a sudden attack may leave him dangerously exposed. When syphilis is suspected, of course most vigorous antisyphilitic treatment must be promptly instituted, and here potassium iodid is most important. Digitalis must be carefully avoided. In the average organic case, the constant use of small doses of potassium iodid is indicated. In functional cases, if digitalis is the cause, of course this must be stopped, and atropin in large doses, gr. 1/100 to gr. 1/60 t. i. d. administered.

PULSUS ALTERNANS (DISTURBANCE OF CONTRACTILITY)

The pulse irregularity here to be considered is not an irregularity of rhythm, as the preceding three classes were, but an irregularity of force, with a maintenance, when uncomplicated, of a normal rhythm. It may, however, appear in combination with other irregularities, especially, extrasystole. The characteristics are shown in Figure 7.

It is there seen that the time interval separating all the systoles is the same, but the height of the systolic waves varies, every high wave being followed and preceded by a low one. All the high waves are of about equal height, and all the low waves are also of about equal height. The venous pulse shows no irregularity.

When, for any reason, the reserve stock of the contractile power of the ventricle becomes exhausted, the ventricle contracts in this alternating manner. Thus, during a strong and prolonged systole (high wave) the period of rest is encroached on, the contractile power is not fully restored and the succeeding beat is a feebler one (low wave). This results in a shorter systole, a longer period of rest becomes possible, and the ventricle so far regains its contractile power as again to be capable of producing a strong beat—and so on.

Factors that unduly increase the work of the heart tend to exhaust its contractile power. Thus we find as causes of this disturbance, old cardiac rheumatism with valvular defects, which thus mechanically embarrass its action; especially mitral stenosis, for in this the nutrition of the ventricular muscle also suffers. Cardiosclerosis, arteriosclerosis, sclerosis of the coronary arteries, chronic nephritis, and cardiac overaction (with marked increase of rate), from any cause. Under the last head, cases of paroxysmal tachycardia are especially to be noted.

This condition is found in middle-aged and elderly individuals, and most commonly with high blood-pressures.

The *subjective symptoms,* though dependent on an exhaustion of contractility, appear while the blood-pressure is still high, and usually while the classical signs of cardiac failure, with the exception of dyspnea, are not manifest. Thus, the blood-pressure is high, the pulse rhythm is regular, there is no cyanosis, no dropsy, and no cardiac dilatation (hypertrophy is usually present). The most distressing symptom is a sense of choking or smothering. There may be substernal oppression or even pain, with radiation to the neck and left arm, and marked palpitation. Sometimes all the syndrome of angina pectoris is manifest. There is a desire for absolute rest, for any movement, by increasing the demand on cardiac contractility, aggravates the distress. The distinctive objective sign of the condition is the alternating pulse.

The *prognosis,* while varying with the underlying cause, is always grave, for in most instances the fundamental pathologic change is permanent, and the function disturbed is the most important of the cardiac functions for the maintenance of the circulatory output. In cases of paroxysmal tachycardia, in which the exciting factor of the attacks of tachycardia is often a neurosis which is amenable to sedative treatment directed toward the nervous system (not forgetting psychotherapy), by removing the exciting cause and this stopping the attacks of tachycardia which are exhausting the contractility, the gravity of the prognosis may be modified.

Treatment consists of rest, mental and physical. All sources of worry must be removed, sleep encouraged, even if hypnotic drugs are required; muscular exertion reduced to a minimum; gastro-intestinal tract kept normal, to avoid flatulence and indicanuria. Excessive blood-pressure must be reduced to the point at which the patient feels most comfortable. No arbitrary rule as to how far to reduce blood-pressure can be given. The most satisfactory dilators are the nitrites in the beginning, to be succeeded by chloral hydrate, gr. v. every 4 hours. In mild cases or for prolonged use potassium iodid, gr. x, t. i. d., is useful. Here again, digitalis must be avoided.

ABSOLUTE IRREGULARITY; PULSUS IRREGULARIS PERPETUUS; AURICULAR FIBRILLATION; NODAL RHYTHM (DISTURBANCE OF TONICITY)

While in the irregularities until now considered the normal rhythm is disturbed, there may be some rhythm to the cardiac action, even though an abnormal one. In the type of irregularity now to be considered, all rhythm is lost. The cardiac action is absolutely disorderly, hence the name "absolute irregularity." With this type of irregularity generally goes a loss of tonicity, an [illegible] esulting from it.

The [illegible] irregularity is now recognized to be dependent on auricular fibrillation. When the wall of the auricle becomes so diseased as to cause this chamber to fibrillate (i. e., the individual fibers undergo independent contraction), the conducting system of the heart is bombarded by impulses begging for passage at the rate of 400 to 900 per minute. This system cannot convey the impulses so rapidly, so that most of them are blocked from passage to the ventricle. The impulses that do pass, however, are usually many more than normal, and they are passed through the conducting system at an irregular rate and in uneven degree. As a consequence, the arterial pulse that results is much more rapid than normal, irregular in both rhythm (or rather without rhythm) and force, the strength of a ventricular contraction not being commensurate with the length of the preceding pause. In venous tracings the *a* wave disappears because the auricle does not undergo any systole, and the resulting venous pulse is of the *ventricular* or positive type, or the *m*-shaped wave. In electrocardiograms, the *p* wave, which represents auricular systole, disappears and the curve bears evidence of fine undulations appearing at the rate of 400 to 900 a minute. In cases of mitral stenosis, a previously evident presystolic murmur disappears with the inception of this arrhythmia.

This type of disturbance may be transient and of short duration, as in some cases of paroxysmal tachycardia, but is most commonly found in chronic cases of rheumatic disease of the valves or myocardium, or old cardiosclerosis cases. Having once appeared, even though for a short time, it will usually reappear, and finally remain permanent. Of patients with valvular disease, mitral stenosis cases are the commonest subjects of this arrhythmia. The degree of irregularity and rapidity of the pulse are usually in direct proportion to each other.

The *symptoms* resulting are those of cardiac failure with loss of tonicity, as dyspnea, orthopnea, dropsy, enlarged liver and congested kidneys and lungs, and often hydrothorax. The heart is found dilated, sounds feeble, irregular and rapid.

The *prognosis* is bad, in so far as there is serious underlying disease, which it is not possible to remove, but we have in these cases a sovereign remedy in digitalis. With the proper use of this drug, which includes a good preparation, freshly made from good leaves, and given in sufficiently large doses, it is specific, so far as the decompensation is concerned. Once cardiac failure from auricular fibrillation is diagnosed, no matter what the size of the heart, no matter what valve lesion is present or not present, digitalis is indicated. If the stomach will tolerate a large potion, the best preparation is a freshly made infusion, given in doses of half an ounce to one ounce two or three times daily, and continued until the desired effect is produced, or until nausea and vomiting are caused. Then the dose must be reduced. If the large potions are too much for the stomach, it will often stand better a good fluidextract given in proportional doses (1 dram of the infusion equals 1 minim of the fluidextract). This constitutes a small dose to take, and may even be given in pill form, in which form it is very well tolerated. So far as drugs are concerned, no other need be considered in this condition, except perhaps to mention magnesium sulphate to produce free catharsis when there is dropsy, and sodium chlorid to be omitted or reduced to a minimum.

Of course, when massive doses of digitalis are indicated, rest is urgently indicated, and this includes reduction of the fluid intake to the minimum amount which is compatible with comfort.

In this condition, the benefit which digitalis exercises is chiefly to be attributed to its stimulating effect on the vagus, thus slowing the ventricular contractions by blocking out some of the numerous impulses which the fibrillating auricle is sending down to the conducting system. The ventricle can thus rest, fill better, and contract more vigorously and to more purpose. The direct stimulation of the ventricular muscle, while perhaps not so marked as the vagus stimulation and not so easily demonstrable, nevertheless does obtain. Digitalis has its most remarkable effect in cases in which the pulse is very rapid before it is used.

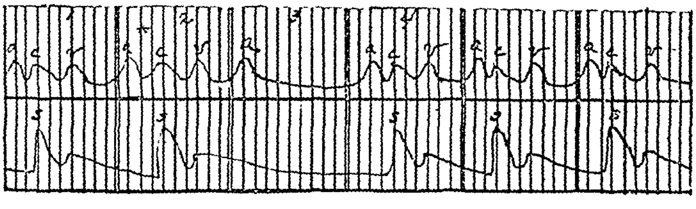

Fig. 6.—Auriculoventricular block. Note absence of response in arterial pulse to auricular contraction, *a* in period 3. Note lengthening of the *a-c* interval, comparing periods 1 and 2, previous to the block, and the shortened *a-c* interval in period 4, which follows the block.

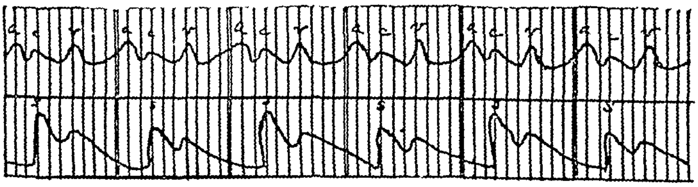

Fig. 7.—Alternating pulse. Note alternate variation in height of systolic waves—*S*, with even time distance between the waves. The venous pulse is normal. *There is here an irregularity of force (contractility) but not of rhythm.*

SUMMARY

To sum up, we must note the following points:

1. A disturbance of cardiac rhythm does not, in itself, indicate a bad prognosis.

2. A disturbance of cardiac rhythm in itself is no indication for the institution of treatment directed to the heart.

3. It is necessary to analyze a cardiac irregularity, so as to determine which of the types mentioned in Table 1 is present, for the prognosis and treatment depend on the type of disturbance. While for purposes of research, close study and further elucidation of the cardiac irregularities, they should be analyzed with the aid of polygraphs and electrocardiograms, it is, nevertheless, in most cases quite possible to determine which type of irregularity we are dealing with by the use of a simple

Jacquet or Dudgeon sphygmograph, instruments that can be conveniently carried in the pocket. Indeed, after a little experience with such an instrument it becomes possible to judge the type of irregularity present by the simple finger palpation of the radial pulse combined with stethoscopic examination of the heart.

4. Do not rush to digitalis as soon as a pulse irregularity is discovered, for in most of the types it is contraindicated.

5. When auricular fibrillation accompanies symptoms of cardiac failure, digitalis is the drug strongly indicated.

6. When, in case of cardiac failure, you are certain that digitalis is required, use it in sufficiently large doses and get a good fresh preparation. The chief reason that the infusion is more often effective than the other preparations is that it is used in larger doses. Thus, few of us prescribe less than half-ounce doses of the infusion, given three times a day, yet few prescribe as high as four minimum doses of the fluidextract three times a day, although it is no more than the equivalent of the half ounce of infusion.

229 West One Hundred and Eleventh Street.

THE INCIDENCE OF SEROFIBRINOUS PLEURISY AND EMPYEMA AS COMPLICATIONS AND SEQUELÆ OF PNEUMONIA, WITH REMARKS ON THEIR MEDICAL TREATMENT *

JAMES M. ANDERS, M.D., LL.D.
AND
ARTHUR C. MORGAN, M.D.
PHILADELPHIA

It is admittedly desirable that the guess methods relating to the incidence of both serofibrinous pleurisy and empyema as complications and sequelæ of pneumonia should give way at the earliest possible moment to exact knowledge. It has been the current professional impression that pleurisy is the most common complication of the pneumonic process, but it must be confessed that there is no available statistical evidence to confirm it fully. Again, the precise definition of the term empyema is free from difficulty, it being applicable to a collection of pus in the pleura, however small, while that of serofibrinous pleurisy secondary to pneumonia is distinctly difficult.

In our view, pleurisy in the clinical sense should be regarded as a complication when it co-exists, either as a severe form of the dry plastic variety with marked friction to auscultation or accompanied by sufficient effusion to be demonstrable by means of the physical signs. On the contrary, the slight dry pleurisy which is ordinarily associated with pneumonia is to be looked on as a part of the usual pathologic picture of the disease.

In all cases in which a pleural exudate is obtainable, an etiologic distinction between the recognized varieties is to be based alone on a bacteriologic examination. In the case of empyema, more particularly when it occurs in children, it may happen that the area of lung-consolidation is small, hence effectually cloaked by the secondary empyemic process. Unless a bacteriologic study is made of all pleural exudates, the cases last described would fail to be recognized as being of pneumococcic or secondary origin.

In general, it may be authoritatively stated that serofibrinous pleurisy is of more frequent occurrence than empyema in lobar pneumonia, a dictum strongly supported by the present statistical inquiries, as will be seen hereafter. It has been found that ante-mortem observations show a smaller percentage of complicating fibrinous and serofibrinous pleurisies relatively than post-mortem figures, for the apparent reason that the lighter graded of these varieties escape observation during the life of the patient. In the case of empyema, however, this discrepancy would appear to be less marked.

A post-mortem examination has frequently revealed an associated pleuritis entirely unsuspected, since this complication often has an insidious onset without either the usual "stitch-like" pain in the involved side or showing any effect on other phenomena belonging to the primary disease. The physical signs, although well-known, merit extended and careful investigation and, should doubt remain as to the diagnosis of complicating pleurisy, an exploratory puncture should be undertaken without delay. It is particularly true of the pleuritis which is secondary to pneumonia in children that while the withdrawn fluid may be serous at first, it soon becomes purulent. The transition, however, is not to be ascribed to a secondary invader but to the action of the pneumococcus.

The statistical observations which form the basis of the present paper embraced an examination of 68,982 clinical and post-mortem records, from which we culled 2,512 cases of pneumonia and found that of these, 1,335 presented complications. In the 2,512 cases of pneumonia, serofibrinous pleurisy occurred in 198 and empyema in 68.

A total of 68,520 clinical case reports, exclusive of 462 post-mortem records, for which no clinical notes could be found, were carefully scrutinized with the following result: Total number of cases of pneumonia, 2,050, in which 890 presented complications and of which 128 were instances of serofibrinous pleurisy and 41 of empyema.

The large number of cases of pleural effusion associated with pneumonia, or 169, in which the date of onset could be determined, promised us the opportunity we desired to determine the relative frequency of the different forms of pleurisy, both during the course of pneumonia and as sequelæ. It was necessary to discard a small proportion in which the notes, especially with relation to time of occurrence of the crisis, were imperfect or failed to show the day of onset of the pleuritis. It is not claiming too much to state that it was necessary to lavish extreme care and patience on the work of scrutinizing the histories in order to determine the date on which the pleurisy or empyema in question in each individual case commenced.

We found that of the 128 cases of serofibrinous pleurisy, 106 occurred as complications and twenty-two as sequelæ, while of the forty-one cases of empyema, twenty-four were classed as complications and seventeen as sequelæ. These figures indicate that serofibrinous pleurisy occurs in 5.12 per cent. as a complication and 1.07 per cent. as a sequel of pneumonia. Serofibrinous pleurisy as indicated by these collective investigations is of much more frequent occurrence secondary to lobar pneumonia than empyema, the ratio being 3 to 1 in favor of the former condition. Empyema occurred in forty-one out of 2,050 cases, or 2 per cent., and it will be observed somewhat more frequently as a complication than as a sequel.

---

* Read in the Section on Practice of Medicine of the American Medical Association, at the Sixty-Second Annual Session, held at Los Angeles, June, 1911.

Considering a total of 462 cases of pneumonia occurring at the Philadelphia Hospital, in which the autopsy records alone were consulted, we found that complications were mentioned in 445 instances, of which eighty-eight or 19 per cent., were pleurisy with effusion, e. g., seventy cases of serofibrinous character and eighteen of purulent character.

An analysis of 858 cases from the same institution, in which the clinical records were also scrutinized, showed complications in 404 cases, of which only thirty-nine were instances of pleural effusion. Of the latter, in thirty-four the exudate was serofibrinous, and in five, purulent. Among the thirty-four cases of serofibrinous pleurisy, twenty-five were classed as complications and nine as sequelæ, while all of the empyemas were complications, i. e., occurring before the crisis.

The total number of records examined at the Protestant Episcopal Hospital (see table) were 1,085. Of these, 464 showed complications, of which 124 were pleurisies, ninety-one serofibrinous and thirty-three purulent. Of the serofibrinous form, seventy-eight were complications and thirteen sequelæ, while of the thirty-three purulent, eighteen were complications and fifteen sequelæ.

The accompanying table will enable the reader to make a ready comparison between the figures obtained from the different institutions, which are there represented; and it also reveals at a glance the total number of records consulted, the number of cases of pneumonia from all sources, the number of instances in which complications were mentioned and the relative number of cases in which serofibrinous and purulent pleurisy, both as complications and sequelæ, occurred.

				Serofibrinous		Purulent	
Name of Hospital	Records Consulted	Total number of pneumonias	Complications mentioned	Complications	Sequelæ	Complications	Sequelæ
Philadelphia General	41,377	858	404	25 (2.9%)	9 (1.05%)	5 (0.58%)	0 .....
Protestant Episcopal	24,795	1,085	464	78 (7.19%)	13 (1.2%)	18 (1.66%)	15 (1.38%)
Medico-Chirurgical ...... (Recent records)	2,348	107	22	3 (0.28%)	0	1 (0.093%)	2 (0.196%)
Total	68,520	2,050	890	106 (5.12%)	22 (1.07%)	24 (1.17%)	17 (0.83%)

The figures of Musser and Norris[1] showing the results of their collective investigations, based on clinical observations, are quite in harmony with those given above. Thus, out of a total of 24,511 cases, studied by them, pleural effusion occurred in 1,535, or 6.26 per cent. On the other hand, the collected cases from autopsy records by these observers are at variance with our own results. For example, they found pleural effusion in 405 out of 974 necropsy records, or 41.58 per cent., while we found in 462 autopsy reports of pneumonia occurring at the Philadelphia Hospital (see above) only eighty-eight instances of pleural effusion, or 19 per cent.

Thomas McCrae stated in a personal communication that out of twenty-nine cases of empyema secondary to lobar pneumonia, twenty-five were classed as complications and only four as sequelæ. These figures indicate a much larger preponderance of empyemata occurring as complications in pneumonia than as sequelæ, thus differing from the results of our collective investigations, e. g., in a total of forty-one cases, twenty-four developed prior to the occurrence of the crisis and seventeen were distinctly postcritical.

TREATMENT

In non-pneumococcic pleurisy of the serofibrinous variety, it is the custom of many clinicians to aspirate early, and we believe that the disease has in the past been too conservatively treated. When we are dealing with either serofibrinous pleuritis or empyema occurring secondary to pneumonia, however, an expectant method, unless thoracentesis be urgently needed, is to be adopted until the crisis has been passed, but if the latter fail to appear at the proper time, then the exudate should be promptly withdrawn. On the other hand, if a critical decline of temperature takes place in due season, a serofibrinous effusion is quickly absorbed in some cases at least, but if not, then recovery must be enhanced by puncture followed by aspiration.

If a massive effusion develop during the fastigium of pneumonia, displacing the heart and other adjacent organs, or if under these circumstances signs of involvement of the non-affected side, such as moist râles, broncho-vesicular breathing and impaired resonance arise, and finally, serious symptoms such as urgent dyspnea or syncopal attacks with cyanosis manifest themselves, the withdrawal of the exudate is to be advised. Such cases, however, may demand more radical operative measures for their cure after the usual crisis, and these should not be too long withheld. Aspiration during the fastigium is a procedure calculated to do harm on account of the slight shock induced by it, hence it should be undertaken only in cases presenting large pleural collections which give rise to the untoward effects already stated.

We desire to state with emphasis that our results from aspiration for pleural effusion in pneumonia prior to the crisis, in patients that have been desperately ill, have been decidedly discouraging.

The aim in the treatment of individual cases of pneumonia in which pleurisy in one of its different forms is associated, is to secure the largest possible degree of comfort to the patient and the withdrawal of the exudate, if it should occur, at the earliest moment compatible with safety to life.

The indications for the use of medicinal substances in complicating pleurisy are few, and nothing in the nature of a depressant, especially such as the coal tar products, is permissible since pneumonia, the primary disease, debilitates every organ of the body, notably the heart. To be avoided also, therefore, are the salicylates, although these as well as quinin and opium exercise a more or less favorable effect in serous pleuritis in general. Opium is also open to objection in the more advanced stages of pneumonia, especially should the bronchi contain secretory products, since the drug exerts a drying effect, thus hindering their dislodgment. A pneumococcus pleuritis may develop and accompany the pneumonic process from the beginning in which case opium may have great usefulness as a therapeutic agent in the earlier stages, relieving the pain and inducing repose.

---

[1] Osler: Modern Medicine, ii, 597.

Experience dictates that quinin has a beneficial influence on inflamed serous membranes, and it possesses a limited value at least, in the pleuritis of pneumonia, both as a supportive agent and in mitigating the intensity of the inflammatory process. It may be administered in 4 gr. doses in capsule, followed immediately by a few drops of dilute hydrochloric acid to insure its prompt solution, four times daily.

LOCAL MEASURES

In cases of pneumonia in which severe pains due to associated pleuritis develop early, fixation of the affected area by means of strips of adhesive plaster is an effective and feasible measure. These should be, however, removed in the event of the occurrence of effusion. The use of morphin in small doses, administered hypodermically, is not objectionable during the earlier stages of pneumonia, if demanded for the relief of intense pains that remain unrelieved by immobilization of the side involved. On the other hand, in light grades of associated pleurisy, counter-irritation by means of sinapisms is to be advised. In the adult, if the patient's nervous system be not too sensitively organized, cold applied in the form of an ice-bag or ice-water bag, or better still cold compresses reapplied at least every hour, as suggested by Baruch, with the least possible disturbance to the patient, is a remedy of choice.

We are quite convinced of the extreme importance of affording prompt relief of the pain, so as to enable the function of respiration to be carried on the more actively, and thus also to preserve the nervous tone and equilibrium of the patient.

In concluding, our best thanks are due to Drs. H. Leon Jameson, Harry W. Bauer and Ernest E. Laubaugh, for material assistance in collecting the statistical data presented above.

1605 Walnut Street.

ABSTRACT OF DISCUSSION

Dr. J. N. Hall, Denver: I wish to comment on a series of sixty-two cases of empyema seen in my private and consultation practice in the past nine years, with a view of urging the necessity of earlier diagnosis. I have to thank my assistant, Dr. T. R. Love, for compiling this brief record. Many of these cases were seen weeks or months after the beginning of the disease, and no less than thirteen of them ruptured through the lung. That is, of course, explained by the fact that in the simple and easily recognized cases operations were done at home, while in many of the obscure the patients came far, often from other states, for investigation. Twenty-two of the sixty-two patients died—a frightful mortality, and far higher than the average, because of the character of the material. Thirty-four of these cases followed an acute pneumonia; eight were found to be tuberculous patients, often originating, doubtless, in pneumothorax; five were associated with bronchopneumonia; three succeeded a simple pleural effusion; three followed an ascending infection from appendicitis; two occurred in cases of measles; two after injury to the chest; while one case was found in association with each of the following conditions: General sepsis; perforation of an infected gallbladder in typhoid fever; gangrene of the lung; sarcoma of the pleura; lipoma of the pleura (no exact cause was determined in the latter two cases). Twenty-nine of the cases were right-sided, thirty were left-sided, while three were not noted. There were forty-four males and but eighteen females.

The earlier and freer use of the exploring needle should prevent such humiliation as we must all feel over such a mortality rate as that quoted, and over such a number of perforations through the bronchi. No case should be allowed to drift with fever and obscure chest symptoms without well-considered and applied exploration. I have finally found pus at the thirteenth puncture under anesthesia in a case in which previous less persistent investigation had failed to reveal it, and the man is well to-day. Yet certain cases of empyema deep in the chest, either between the lobes or on the diaphragm, may go on to rupture or death without such external signs as to lead to their detention even by fairly expert clinicians. Such instances should, however, be rare. I wish to reiterate the importance of more persistent attempts to find the pus in cases of obscure chest disease, with fever and leukocytosis, and to urge the danger underlying the diagnosis of "unresolved pneumonia," "thickened pleura," etc. If not cleared up by one or two punctures, it is better, if we can be reasonably certain that pus is present somewhere in the chest, to give an anesthetic with everything prepared for operation and systematically explore the chest until pus is found. The drainage by the surgeon is often a far less formidable procedure than the finding of the purulent focus. We have from 15 to 20 per cent. of the total population of Denver who have come to us because of some form of disease; many of them have some changes in the chest such as an empyema, or the results of perforation, or lung abscess. I have seen a general streptococci infection resulting from the injection of some sort of a vaccine. It was afterwards learned that the needle was stuck into the lung; as a result an empyema developed and the patient died. As to any damage to the lung itself by exploration, I have never seen serious trouble.

Dr. Everitt J. Brown, Decatur, Ill.: I think there is one crime which we can frequently hold against the general practitioner and that is the failure to recognize fluid in the chest. In consultation work in a country district I find many cases of empyema and other pleuritic exudates unrecognized. I recently saw a case of empyema in a young man, age 16 years, in which the amount of pus was so enormous as to cause actual deformity from the bulging of that side of the chest. I removed 7 pints by aspiration on one day and three days later 8 pints more were removed by drainage. The patient made a good recovery. I recently had two cases of empyema occur simultaneously in the same family; both were young men. The first case followed pneumonia, and the second boy became infected from the first case by blowing through the tubes attached to a James bottle which the first patient was using to expand the lung; pneumonia with empyema which required drainage occurred. Both patients recovered.

Dr. C. F. Hoover, Cleveland: A very good practice in examining patients with suspected disease of the pleuræ is to auscultate with the unaided ear. If this practice is adhered to it will be found that every accumulation of fluid in the pleural cavity causes an elevation of pitch of the murmur of inspiration and expiration. The sound may be faint or at times inaudible on account of thickening of the pleuræ, but when the respiratory sounds are audible they are heightened in pitch by the presence of fluid whether it is pus, blood or serum.

Dr. A. C. Morgan, Philadelphia: The discussion, it seems to me, has resolved itself into a study of the physical signs. It has, however, been immensely profitable. In the paper presented there were without any doubt many sins of omission as well as of commission; these may occur in attempts at making a diagnosis of a pleuritic exudate, no matter of what type, and may occur through carelessness or through ignorance, or through an improper interpretation of what is found in the physical examination of the chest. In teaching physical signs in the chest to students I have found that it is very hard to get them to study those that are normal; but they are always very eager to study the signs that are abnormal. Place a student to examine a normal chest and he soon assumes an air of satiety; he turns from it and it is very hard to keep his attention. But when given a chest to examine that is abnormal he is delighted and listens to what can be heard, although he is not fitted to interpret properly what he finds. I think, too, that general practitioners have this same fault; they will not study the normal conditions found in the chest; they do not maintain in their minds what is real and what is abnormal. The best way, I believe, to teach what is abnormal is first to insist on the students being taught what is the normal. They should be made to learn what is the normal; they should be made to become familiar with the normal conditions. If you can satisfy yourself that you know what is normal, then when you strike something that is abnormal, your interest will be aroused, and you will proceed to study the case along definite and concrete lines. I wish to make a plea that we get back of this and learn first the normal; then when we find something that is not normal we shall be in a better position to study our cases intelligently.

EOSINOPHIL CELLS AND POLLEN IN VERNAL CATARRH

BROWN PUSEY, M.D.
CHICAGO

In April, 1911,[1] I reported the finding of eosinophil polymorphonuclear leukocytes in smears taken from a series of cases of vernal catarrh, confirming Herbert's discovery. Interested in this finding and knowing the many points of similarity between vernal catarrh and the conjunctivitis of hay-fever, I have been led to the examination of smears taken from a series of cases of the latter disease.

In smears taken from the conjunctivæ of a series of cases of hay-fever, I have found eosinophil polymorphonuclear leukocytes in great abundance; indeed the cellular content of a smear from the one disease is the same as that from the other.

This observation shows another, and possibly a very important, similarity between the two diseases. We know that the conjunctivitis of hay-fever is due to pollen. From my observation of eosinophil cells in the conjunctival secretion of hay-fever, we know that pollen may cause an inflammation of the conjunctiva with secretion containing an abundance of eosinophil cells. This fact becomes of increased interest when it is realized that eosinophil cells are a negligible factor, as was shown in my previous work, in smears from all ordinary forms of conjunctivitis.

It is in the field of etiology of vernal catarrh (an unknown field) that the finding of these cells in hay-fever is of interest. I venture to think that the presence of eosinophil cells in the conjunctivitis of hay-fever and in vernal catarrh, and their absence in ordinary forms of conjunctivitis, point strongly to a similar etiologic factor—pollens.

7 West Madison Street.

Screw-Worms in the Ear.—Dr. W. S. Lorimer, Handley, Tex., writes: "A few days ago I was called to see a female child, 4 months old, who had been peevish and fretful for two days previous. She was well nourished, apparently healthy, being breast-fed and having healthful and sanitary surroundings. The history was negative, except for irritability and fretfulness for two days. There had been no previous illness. On examination, a small, white, moving object was seen in right ear, which proved later to be a screw-worm. Chloroform was applied to the ear, and, on irrigating with boric acid solution, three screw-worms came out. The child recovered and is well and healthy. I cannot imagine how this condition can occur in children in such sanitary surroundings."

AN ARTHROPLASTIC OPERATION FOR HAMMER-TOE

B. J. O'NEILL, M.D.
SAN DIEGO, CAL.

The following case is reported both on account of the good result secured and because, so far as is known to me, it is the first attempt to adapt Murphy's arthroplastic operation to hammer-toe.

History.—The patient, a woman of 22, came to me in January, 1911, with a hammer-toe, which had been present since childhood and which caused her great pain on walking.

Examination.—The third toe of the left foot was a typical and very marked hammer-toe, with a tender callus on the top of the first and on the bottom of the second joint, the adjoining toes almost touching in front of the vertical second phalanx and above the terminal phalanx, and an almost complete ankylosis of the first phalangeal joint. A general examination was negative.

Treatment.—I advised amputation, which was refused. As the patient insisted on trying some conservative operation, it occurred to me that the operation I had seen Dr. J. B. Murphy do on an ankylosed knee-joint might be repeated on a small scale here.

Operation.—Accordingly, under general anesthesia, I made a longitudinal incision about an inch long on the dorsal surface of the toe, its middle over the prominence of the joint, freed the bone from the soft parts, and removed the distal end of the first and the proximal end of the second phalanx for a distance of about one-fourth inch each. I then dissected loose a thin layer of the subcutaneous tissues at the outer side, cut it loose at its distal end so as to make a flap with the pedicle at the proximal end, passed this across between the two bones and sutured it by one stitch each to the inner side, below and above. I then closed the skin wound with a subcuticular silkworm gut and fastened foot and toe by adhesive strips to a specially prepared splint in such a way as to hold the toe perfectly straight.

Result.—Immediately after the operation, the joint was flail-like and the soft parts loose and baggy, but they gradually contracted down and backward, making the toe slightly shorter than its fellows and but little above the normal size. It remained tender for some time but this soon passed over and the healing was complete in about three weeks. I had feared recurrence on account of the pinching in of the toes on either side but the slight shortening of the toe seems to have prevented this. At the present time, six months after the operation, the toe is only slightly thickened at this joint, straighter than any other toe on the foot, and gives the patient no pain or discomfort whatever. There seems to be a new joint developed at the point, as there is fully as much mobility, both active and passive, as in the other toes.

Sefton Block.

Therapeutics

PRESCRIPTION WRITING

(Continued from page 1135)

CHAPTER II.—OFFICIAL PREPARATIONS

The principal preparations of the United States Pharmacopeia may be classified as follows:

1. Solids mostly for internal use:
    - A. Extracts (extracta).
    - B. Pills (pilulæ).
    - C. Powders (pulveres).

2. Liquids mostly for internal use:
    - A. Waters (aquæ).
    - B. Elixirs (elixira).
    - C. Emulsions (emulsa).
    - D. Fluidextracts (fluidextracta).
    - E. Infusions (infusa).

---

[1] Pusey, Brown: Vernal Conjunctivitis and Eosinophil Cells, THE JOURNAL A. M. A., April 1, 1911, p. 952.

F. Liquors (liquores).
G. Mixtures (misturæ).
H. Spirits (spiritus).
I. Syrups (syrupi).
J. Tinctures (tincturæ).

3. Semisolids for external use:
A. Cerates (cerata).
B. Ointments (unguenta).

4. Liquids for external use:
A. Liniments (linimenta).
B. Some waters (aquæ).
C. Some liquors (liquores).
D. Some tinctures (tincturæ).

1. Solids Mostly for Internal Use

A. *Extracts* are concentrated preparations of a drug, and are mostly moist and sticky. A few extracts are dry. They should be prescribed in pill or capsule.

The most important are:

Extractum belladonnæ foliorum	Dose. 0.01 gm. or gr. 1/6
Extractum digitalis	Dose. 0.01 gm. or gr. 1/6
Extractum ergotæ	Dose. 0.25 gm. or gr. iv
Extractum nucis vomicæ	Dose, 0.01 gm. or gr. 1/6
Extractum physostigmatis	Dose, 0.01 gm. or gr. 1/6
Extractum rhamni purshianæ	Dose. 0.25 gm. or gr. iv
Extractum opii	Dose. 0.03 gm. or gr. 1/2

B. Official *pills* are ready-made preparations, and consequently it should be remembered that they may have deteriorated or become more or less insoluble. Still some of the laxative pills, especially, are of value.

The following is a ready reference to the ingredients of the most used pills:

Blaud's pills (pilulæ ferri carbonatis) contain 0.065 gm. (1 gr.) of iron.

Pills of aloes (pilulæ aloes) contain 0.13 gm. (2 gr.) of aloes.

Pills of aloes and iron (pilulæ aloes et ferri) contain 0.065 gm. (1 gr.) each of aloes and iron.

Compound cathartic pills (pilulæ catharticæ compositæ) contain extract of colocynth comp. 0.08 gm. (1¼ gr.); calomel 0.06 gm. (1 gr.); resin of jalap 0.02 gm. (⅓ gr.); gamboge 0.015 gm. (¼ gr.).

Vegetable cathartic pills (pilulæ catharticæ vegetabiles) contain extract of colocynth comp. 0.06 gm. (1 gr.); extract of hyoscyamus 0.03 gm. (½ gr.); resin of jalap 0.02 gm. (⅓ gr.); extract of leptandra 0.015 gm. (¼ gr.); resin of podophyllum 0.015 gm. (¼ gr.).

Compound laxative pills (pilulæ laxativæ compositæ) contain aloin 0.013 gm. (1/5 gr.); strychnin 0.0005 gm. (1/120 gr.); extract of belladonna leaves 0.008 gm. (⅛ gr.); ipecac 0.004 gm. 1/15 gr..

Compound podophyllum pills (pilulæ podophylli, belladonnæ et capsici) contain resin of podophyllum 0.016 gm. (¼ gr.); extract of belladonna leaves 0.008 gm. (⅛ gr.); capsicum 0.032 gm. (½ gr.).

Compound rhubarb pills (pilulæ rhei compositæ) contain rhubarb 0.13 gm. (2 gr.); aloes 0.10 gm. (1½ gr.); myrrh 0.06 gm. (1 gr.).

C. Official *powders* are dry preparations of two or more drugs. It is better to order a powder by its official title, but below are the common names and the ingredients of the most used of these preparations:

Dover's powder (pulvis ipecacuanhæ et opii) contains 10 per cent. each of ipecac and opium.

Tully's powder (pulvis morphinæ compositus) contains 1.5 per cent. of morphin and 32 per cent. of camphor.

Compound aromatic powder (pulvis aromaticus) is a mixture of aromatics.

Compound jalap powder (pulvis jalapæ compositus) contains 35 per cent. of jalap and 65 per cent. of potassium bitartrate.

Compound licorice powder (pulvis glycyrrhizæ compositus) contains 18 per cent. of senna; 23 per cent. of glycyrrhiza; 8 per cent. of sulphur.

Gregory's powder, compound rhubarb powder (pulvis rhei compositus) contains 25 per cent. of rhubarb; 65 per cent. of magnesium oxid; 10 per cent. of ginger.

Seidlitz powder (pulvis effervescens compositus) consists of two powders; one of Rochelle salt and bicarbonate of soda in blue paper, and the other of tartaric acid in white paper.

2. Liquids Mostly for Internal Use

A. *Waters* are solutions of *volatile* substances in *water;* mostly *weak* preparations. (Exception, ammonia waters.)

H. *Spirits* are solutions of *volatile* substances in *alcohol;* mostly *strong* preparations. (Exception, sweet spirits of niter.)

F. *Liquors* are solutions of *non-volatile* substances in *water;* mostly *weak* preparations. (Exceptions, the arsenic solutions and those for external use.)

J. *Tinctures* are solutions of *non-volatile* substances in *alcohol;* mostly *strong* preparations. (Exceptions are the aromatic and stomachic [bitter] drug tinctures.)

H. Some of the common names of spirits are:

Whisky (spiritus frumenti).
Brandy (spiritus vini gallici).
Sweet spirits of niter (spiritus ætheris nitrosi).

F. Some of the common names of liquors are:

Fowler's solution (liquor potassii arsenitis).
Spirit of Mindererus (liquor ammonii acetatis).
Lugol's solution (liquor iodi compositus).
Goulard's solution (liquor plumbi subacetatis).
Labarraque's solution (liquor sodæ chlorinatæ).

B. *Elixirs* are sweetened liquid preparations containing alcohol. They are weak preparations, and the National Formulary contains a large number.

C. *Emulsions* are liquid preparations containing a suspended oil.

D. *Fluidextracts* are liquids representing exact strengths of the drugs, i. e., 1 cubic centimeter (15 minims) contains the medicinal properties of 1 gram (15 grains) of the drug.

E. *Infusions* are weak watery preparations. One only is of value, viz., infusum digitalis.

G. *Mixtures* are liquids containing more than one drug, often an insoluble one. The most used are:

Brown mixture (mistura glycyrrhizæ compositus).
Chalk mixture (mistura cretæ).

The National Formulary contains a long list of mixtures.

I. *Syrups* are very sweet watery solutions of one or more drugs. These weak preparations are prescribed too frequently, as they readily cause disturbance of the stomach, and do not often modify a bad-tasting drug, but may even protract the taste. Sweet cough syrups are an abomination.

3. Semisolids for External Use

A. and B. The principal difference between *cerates* and *ointments* is their melting-points. The ointments contain more lard or petroleum fat and less wax than the cerates, hence they have a lower melting point than the latter. Cerates do not melt when applied to the skin.

4. Liquids for External Use

Some *waters,* some *liquors,* some *tinctures* and the *liniments,* as the name implies, are used externally only. Most of the liniments are stimulating to the skin, but two being sedative, viz., the belladonna liniment and the carron oil (linimentum calcis).

(To be continued).

New and Nonofficial Remedies

The following additional articles have been accepted by the Council on Pharmacy and Chemistry of the American Medical Association. Their acceptance has been based largely on evidence supplied by the manufacturer or his agent and in part on investigation made by or under the direction of the Council. Criticisms and corrections are asked for to aid in the revision of the matter before publication in the book "New and Nonofficial Remedies."

The Council desires physicians to understand that the acceptance of an article does not necessarily mean a recommendation, but that, so far as known, it complies with the rules adopted by the Council.

W. A. Puckner, Secretary.

PEROXIDES OF METALS

Metallic peroxides are compounds in which the hydrogen of hydrogen peroxide has been replaced by metals, and which are readily decomposed with liberation of hydrogen peroxide, or of oxygen in an active state. The peroxides of several metals have been suggested as substitutes for the hydrogen peroxide solution, official as aqua hydrogenii dioxidi.

The commercial products are usually mixtures containing but a limited amount of real peroxide; for example, commercial "magnesium peroxide" contains but about 15 per cent. of magnesium peroxide while commercial "sodium peroxide" contains about 75 per cent. of sodium peroxide.

The different peroxides vary considerably in their stability, their solubility and in their ease of decomposition in solution. In solutions of acids the peroxides are decomposed, forming hydrogen peroxide and the salt of the metallic radicle of the peroxide. In this way the entire active oxygen-content of the peroxide is quickly made available in the form of hydrogen peroxide in solution. Water dissolves only minute quantities of these peroxides, but it decomposes them with varying degrees of readiness. Thus zinc peroxide, although very insoluble, is decomposed by water into zinc hydroxide and hydrogen peroxide as follows:

$$ZnO_2+2H_2O \rightarrow Zn(OH)_2+H_2O_2$$

The energy of the oxidizing powers of different peroxides varies in direct ratio to the alkalinity of the solution produced in their decomposition. The variation in the alkalinity of the solutions formed affects the therapeutic uses of the peroxide. Sodium peroxide is not desirable for therapeutic use because of the formation of the strongly alkaline solution of sodium hydroxide (caustic soda). Magnesium and zinc peroxide, on the other hand, yield weakly alkaline solutions and are for that reason more desirable.

Actions and Uses.—Like hydrogen peroxide, the metallic peroxides depend for their value on the readiness with which a part of their oxygen becomes active. They are claimed to possess advantages over solution of hydrogen peroxide, because the oxygen is set free more gradually. Among themselves the metallic peroxides differ in their action in accordance with their solubility and the alkalinity produced by interaction of the peroxid with water. The action of peroxides is also affected by the nature of the metal which goes into solution when the peroxid is decomposed. Thus the use of sodium peroxide is limited by the strong base formed when it dissolves in water and that of zinc peroxide by the poisonous action of zinc solutions.

Because of the strong oxidizing effects on the lower organisms, the peroxides have been recommended as a convenient means of sterilizing water, thus a mixture has been used containing magnesium peroxide 0.2 Gm. and tartaric acid 0.5 Gm., the latter favoring the decomposition of the peroxide. It has been proposed to employ the oxidizing effect of peroxides in the treatment of skin diseases, by using a mixture of zinc peroxide, 10 parts; potassium iodide, 5 parts, and tartaric acid, 1 part from which on contact with moisture iodine is gradually liberated. As an ingredient of dentifrices magnesium and strontium peroxide have been used.

Internally the peroxides have been claimed to be of value as gastric and intestinal antiseptics and to be of use in the treatment of acid dyspepsia, abnormal fermentation and summer diarrhea of infants.

CALCIUM PEROXIDE—Calcii Peroxidatum.—Calcium peroxide is a mixture consisting essentially of calcium peroxide, the calcium salt CaO_2, of hydrogen peroxide and calcium hydroxide and carbonate, containing not less than 60 per cent. calcium peroxide, equivalent to 13.4 per cent. available oxygen.

Calcium peroxide is a light, cream-colored, odorless and tasteless powder. It is practically insoluble in water, but by such contact it is gradually decomposed into hydrogen peroxide and calcium hydroxide, the hydrogen peroxide being further decomposed by the alkaline calcium hydroxide with liberation of oxygen. It is decomposed by dilute acids with formation of a solution containing hydrogen peroxide.

If a few milligrams of calcium peroxide be shaken with 10 Cc. water and 1 drop diluted sulphuric acid, and a few Cc. ether added, the subsequent addition of a drop of potassium dichromate solution will produce a blue color in the aqueous layer. On shaking, the blue color will pass into the ethereal layer.

If 1 Gm. calcium peroxide be dissolved in 25 Cc. dilute nitric acid and 2 Cc. tenth-normal silver nitrate added to the solution and the resulting precipitate filtered off, the further addition of a few drops of silver nitrate solution to the filtrate should produce not more than a turbidity.

If 1 Gm. calcium peroxide be exposed to the full heat of a Bunsen flame for five minutes, then dissolved in 25 Cc dilute hydrochloric acid and the solution made up to 100 Cc., a solution will result which will conform to the following tests:

Ten Cc. of the solution, to which ammonium hydroxide in excess has been added, should yield a white precipitate on the addition of ammonium oxalate solution.

Ten Cc of the solution saturated with hydrogen sulphide should yield no precipitate, nor become colored.

Ten Cc. of the solution should yield not more than a turbidity on the addition of barium chloride solution.

Ten Cc. of the solution, after addition of a slight excess of ammonium hydroxide and acidification with acetic acid, should yield no turbidity on the addition of potassium dichromate solution.

If 0.2-0.3 Gm. calcium peroxide, weighed into a flask, be shaken with 25 Cc. water, then 25 Cc. dilute hydrochloric acid added, the titration of this solution with tenth-normal potassium permanganate should indicate the presence of not less than 60 per cent. calcium peroxide. (One Cc. tenth-normal potassium permanganate is equivalent to 0.0036 Gm. CaO_2).

Actions and Uses.—See Peroxides.

Dosage.—0.06 to 0.3 gm. (1 to 5 grains) in water or with sodium bicarbonate, two to three times daily.

Calcium Peroxide, R. & H.—Manufactured by the Roessler & Hasslacher Chemical Co., New York. Not patented or trademarked.

MAGNESIUM PEROXIDE.—For properties, actions, uses and dosage see New and Nonofficial Remedies; also The Journal A. M. A., Feb. 25, 1911, p. 591.

Magnesium Peroxide, R. & H.—Manufactured by Roessler & Hasslacher Chemical Co., New York. Not patented or trademarked.

SODIUM PEROXIDE.—For properties, actions, uses and dosage see New and Nonofficial Remedies, 1911, p. 209.

STRONTIUM PEROXIDE—Strontium Peroxidatum.—Strontium peroxide is a mixture consisting essentially of strontium peroxide, the strontium salt, SrO_2, of hydrogen peroxide and strontium hydroxide containing at least 84.5 per cent. strontium peroxide, equivalent to 11.3 per cent. available oxygen.

Strontium peroxide is a fine, white, odorless and tasteless powder. It is practically insoluble in water, but by such contact is gradually decomposed into hydrogen peroxide and strontium hydroxide, the hydrogen peroxide being further decomposed by the alkaline strontium hydroxide with liberation of oxygen. It is decomposed by dilute acids with formation of a solution containing hydrogen peroxide.

If a few milligrams of strontium peroxide be shaken with 10 Cc. water and 1 drop dilute sulphuric acid, and a few Cc. of ether added, the subsequent addition of a drop of potassium dichromate will produce a blue color in the aqueous layer. On shaking, the blue color will pass into the ethereal layer.

If 1 Gm. strontium peroxide be dissolved in 25 Cc. dilute nitric acid and 2 Cc. tenth-normal silver nitrate added to the solution and the resulting precipitate filtered off, the further addition of a few drops of silver nitrate solution to the filtrate should not produce more than a turbidity.

If 1 Gm. strontium peroxide be exposed to the full heat of a Bunsen flame for five minutes, then dissolved in 25 Cc. dilute hydrochloric acid and the solution made up to 100 Cc., a solution will result which will conform to the following tests:

Ten Cc. of the solution made alkaline by the addition of ammonium hydroxide and then slightly acid with acetic acid should yield a white precipitate on the addition of ammonium sulphate solution.

Ten Cc. of the solution saturated with hydrogen sulphide should yield no precipitate nor become colored.

Ten Cc of the solution should yield not more than a turbidity on the addition of barium chloride solution.

Ten Cc. of the solution which has been made alkaline with ammonium hydroxide and then acidified with acetic acid should yield no turbidity on the addition of potassium dichromate solution.

If 0.2-0.3 Gm. strontium peroxide, weighed into a flask, be treated with 50 Cc. water and dissolved by addition of 20 Cc. dilute sulphuric acid, the titration of this solution with tenth-normal potassium permanganate should indicate the presence of not less than 84.5 per cent. strontium peroxide. (1 Cc. tenth-normal potassium permanganate is equivalent to 0.0061 Gm. SrO_2).

Actions and Uses.—See Peroxides.

Dosage.—It is used in the form of ointments and as a dusting powder.

Strontium Peroxide, R. & H.—Manufactured by the Roessler & Hasslacher Chemical Co., New York. Not patented or trademarked.

ZINC PEROXIDE.—For properties, actions, uses and dosage, see New and Nonofficial Remedies, 1911, p. 234.

Zinc Peroxide, R. & H.—Manufactured by the Roessler & Hasslacher Chemical Co., New York. Not patented or trademarked.

THE PROGRESS OF CHEMOTHERAPY

In an address before the society of microbiology in Dresden[1] last May, Ehrlich drew back the curtain and gave several glimpses of the seething activity with which the new field of chemotherapy is being cultivated at the laboratories in Frankfort. Only one who is familiar with the difficulties and obstacles to be overcome at both the chemical and experimental ends of this work, can fully appreciate the enormous energy and tireless industry to which the abundant results that pour out from the Ehrlich institutions testify.

Evidently the immunity or resistance which parasites acquire to both chemical parasiticides and immune serums has occupied much of the attention of the investigators. Biologists will find much to interest them in the demonstration that once a strain of parasites has acquired such immunity, the descendants of this strain will continue to exhibit the acquired characteristic for an indefinite number of generations, through years at least. Physicians will see in this fact a justification of the fear, which was aroused early in the study of chemotherapy, that in time we may become the prey of parasites which are immune to every known sort of parasiticidal agent. Happily, Ehrlich has discovered that this danger is not imminent, and perhaps our fears are entirely groundless; the escape lies through another observation of profound biologic interest, which may be described as follows: As long as a strain of a parasite immune to a given poison is perpetuated by direct passage from animal to animal, the reproduction is asexual, and the protoplasm is directly continued from generation to generation: in this case the immunity persists. But if by passage through a natural intermediate insect host the parasite is reproduced through sexual conjugation, the new generations are devoid of the acquired specific immunity to the parasiticidal drug. Therefore, since most of the protozoan diseases, at least, are transmitted through intermediate hosts, it is probable that the danger of perpetuation of drug-immune parasites is not serious.

Parasites become immune to serum antibodies much more quickly than to chemical parasiticides, but the immunity to the chemicals is much more difficult to eliminate by experimental means. According to Ehrlich's views, when a parasite becomes refractory to an immune serum it does so by developing new groups of receptors to take the place of those occupied by the antibodies, these receptors being the same receptors as combine with the food materials, and hence called "nutriceptors." But it is possible for the host to develop new antibodies specific for the newly developed receptors, and this alternate counter-immunization may continue until the parasite has exhausted all possible means for producing the new receptors necessary for maintenance of nutrition, when it will be obliged to die out because the serum of the host contains all the different forms of antibodies necessary to combine all the different receptors of the parasite. Experimental evidence has been obtained on which this conception of the counter-reaction of host and parasite is based, and also it has been found that the number of new recurring strains which most parasites can develop is, fortunately, quite limited. To prevent the development of these immune strains it is desirable to produce a complete sterilization of the host with one dose of the therapeutic agent, if possible, but if a parasiticidal agent kills only a fraction of the parasites it still may happen that the antibodies formed in reaction to the killed organisms will be sufficient to destroy the survivors; on this account it may sometimes happen that a therapeutic injection will give more complete destruction of the parasites when these are present in large numbers than it will at earlier stages of the disease when but few parasites are present.

In syphilis the decreasing number of organisms present as the disease advances may be ascribed to the wiping out by specific antibodies of most of the strains present, leaving a few survivors refractory to all the antibodies developed by the host up to that time. The fresh outbreaks of syphilitic lesions are, on this basis, brought about by new strains of the spirochete which have developed immunity to the existing antibodies, and the subsidence of the lesions depends on the formation of a new set of antibodies to combat the new strain. Hence it comes to pass that during the actual existence of syphilitic infection the individual is not susceptible to a new infection, because of the abundance of antibodies present in his blood to which the new strain of spirochetes is not immune. But when the disease is over and the antibodies have been eliminated, reinfection becomes possible. The recurrence of lesions after salvarsan injections, especially in certain nerves, is ascribed by Ehrlich, not to an injury of the nerve tissue by the drug, but to an actual syphilitic lesion set up by organisms present in the nerves, where they are somewhat protected from the salvarsan, so that after the drug has been sufficiently eliminated they multiply and set up local lesions. The best protection against this form of complication will be early treatment, before such localization has occurred.

---

1. Ehrlich: Folia Serologica, 1911, vii, 697.

Certainly this address, as well as the numerous papers that have recently appeared from Ehrlich's workshops, carries the conviction that the progress in chemotherapy is being based on most sound and careful experimental work, and that as yet this work, large as its results already are, is still in the earliest preliminary stages. We have every right to look for more brilliant results in the future. The fear expressed that in diseases with local lesions chemotherapy must be less successful than in such blood infections as trypanosomiasis and similar diseases with which most of the experiments have been conducted, is already discounted by the highly successful results obtained by many in the treatment of frambesia or yaws.

STANDARDIZATION OF ERGOT

Another important contribution[1] to the subject of the physiologic standardization of drugs has been made by the Hygienic Laboratory of the Public Health and Marine-Hospital Service. The authors conclude, both from their own work and from that of others, that the proposed chemical methods of assay throw little light on the therapeutic value of a preparation of ergot. This view seems now to be accepted by most manufacturers. Thus a member of a firm which has been laying much emphasis on the fact that its product was assayed by the cornutin of Keller (which, the firm said, it had found to be a "trustworthy guide as to the therapeutic strength of the drug"), states that "he has come to the conclusion that cornutin assay is not a criterion of therapeutic value."

Three principal methods have been proposed for the physiologic standardization of ergot, the cock's comb, the uterine, and the blood-pressure methods; all are in use and the chief object of the present work was to determine which is the most trustworthy. Inasmuch as ergot is ordinarily used for the purpose of influencing the activity of the uterus, the authors considered that a method based on the effects of the drug on this organ would have the most value. They found that different observers, working independently of each other, were by this method able to obtain concordant and satisfactory results. It is, however, tedious and somewhat expensive, and the authors were gratified to find a close parallelism between the results obtained by this method and those obtained by the "cock's comb method," which was introduced into this country some years ago by Houghton. No constant relation was found between the results obtained by these methods and the effects on the blood-pressure, a result readily explained by the fact that ergot contains, in varying amounts, certain amins which have a greater action, proportionately, on the blood-pressure than on the uterus.

The authors recommend for practical purposes, the cock's comb method. It is suggested that ergotoxin, one of the alkaloids of ergot, may be taken as a standard and that the strength of fluidextracts may be adjusted so that 2 c.c. equals in physiologic action 5 mg. of ergotoxin.

The primary object of the bulletin was to test the value of the various methods. The subject in which the practitioner is most interested, the comparative value of the preparations of ergot on the American market, received less attention; but some of the results are of much interest from this point of view. The preparations examined consisted in fluidextracts, prepared by the authors themselves, and in commercial preparations purchased on the open market in both Washington and Ann Arbor. In addition certain specimens were obtained directly from the manufacturers. The fluidextracts made by the authors themselves according to the U. S. P. were more active (usually from two to four times as active) as the commercial fluidextracts. Such results suggest that a reliable pharmacist following the official method may be able to supply the physician with as good preparations as the large manufacturing houses, or even better. The authors remark that the fact of the commercial preparations being usually inferior need not be considered a reflection on the manufacturers, as it may be merely the result of aging, but that in view of this deterioration it would be desirable for the date of manufacture to be stated on the bottles.

The case is different, however, with a number of special, proprietary preparations, for these are generally claimed to be permanent and often to be much more active than the official preparations. The most active of the special preparations examined was "cornutol," which was found to be as active as the best fluidextract; it is claimed, however, to be two and one-half times as active as the latter. If this statement be true of this preparation, the specimen examined had evidently undergone deterioration. The "concentrated purified ergot" of another firm was found to be only about three-fourths as active as a good fluidextract. A specimen of "ergotole" was found to be only one-third as strong as a good fluidextract although the manufacturers claim it to be two and one-half times as strong as the latter; much emphasis is laid by the manufacturers on its being a "permanent solution" which "does not change with age," and is "therefore always reliable." Two samples of "ergone," another proprietary preparation claimed to be "permanent," were examined. The sample obtained directly from the manufacturer was somewhat more than half as active as the authors' fluidextract; the other sample, obtained through the usual channels of trade, was almost devoid of physiologic activity. The "permanent" preparation had evidently deteriorated greatly.

Although, as was said above, the authors do not lay especial emphasis on the results obtained with the commercial preparations, being chiefly interested in the general principles involved, these are sufficient to emphasize the need of far more care and accuracy on the part of manufacturers, both as to their preparations and the claims made for them.[2]

[1] Edmunds, C. W., and Hale, Worth: The Physiological Standardization of Ergot, Hy; Lab. Bull. 76. This bulletin may be obtained by addressing the Surgeon-General of the P. H. and M.-H S.

It is doubtful whether uniform preparations of ergot and digitalis will be available until the U. S. Government adopts a system of continuous control similar to that which has proved so satisfactory in the case of antitoxins, vaccine virus, etc.; manufacturers are failing to supply satisfactory preparations of these drugs just as they failed to supply antitoxins, etc., of uniform value until the passage of the law placing them under the control of the Public Health and Marine-Hospital Service.

THE GRAND CLIMACTERIC IN MAN

That man, passing through life, is subject in certain years to special dangers is an idea now tenaciously held by many, and one which, since very early times, seems to have appealed to the minds of both medical and lay observers. The antiquity of the conception is illustrated by the etymology of the word "climacter"; it is derived from the Greek κλιμακτήρ which means literally, "a step of a stair-case or ladder," though it was used also to designate "a dangerous period of life." References to "climacterical years," or to the "grand climacteric," are to be found in the writings of older English authors, including Sir Thomas Browne in his "Vulgar Errors," Massinger in "The Old Law," and Burke in his "Reflections." Every seventh or ninth year was considered dangerous, most of all the sixty-third year of a man's life.

That some relation exists between certain of these critical periods and the sexual functions has also long been maintained. In both male and female, the fourteenth year corresponds approximately to puberty, and, in woman, the forty-second, or the forty-ninth year, is not uncommonly the date of the menopause. In man, at the age of sixty-three—his *grand climacteric*—some assume that, owing to the cessation or marked diminution of the activity of the testicles, a profound change takes place in the body and that this change corresponds closely to that supposedly dependent on the more sudden alteration in the function of the ovaries at the menopause in woman.

That certain tolerably characteristic symptoms, not unlike those presented by women at the "change of life," are undoubtedly manifest in many men at about the age of sixty-three, will be vouched for not only by physicians in general practice, but also, particularly, by nerve-specialists, to whom the patients ordinarily turn for relief. On the symptoms referred to attention has recently been focused again in the articles of Mendel[1] and of Fürst.[2] The most striking of the disturbances attributed to the *climacterium virile* are a certain lack of emotional control and a tendency to shed tears, combined with more or less outspoken signs of depression, disinclination for exertion, lack of will-power, and irritability. Other symptoms, sometimes prominent, are dizziness, a sense of pressure in the head, hot flushes, and palpitation of the heart.

In connection with these observations the questions at once arise whether these symptoms are, in reality, due to a disturbance of internal secretion of the testicles, or whether they can be the result of the arteriosclerosis which develops, almost with regularity, at about this age, and if there may not possibly be a relation between testicular function and vascular integrity in the male. In the present state of science these are queries not at all easy to answer.

Those who defend the doctrine of the sexual origin of the male climacteric point to the nervous emotional and vasomotor phenomena which follow castration, analogous to the menopause symptoms artificially called forth in women by double oophorectomy. Though they admit the plausibility of the objection that the natural male climacteric may depend on arteriosclerosis rather than on retrogression of the activity of the sexual glands, they argue that the arteries are not always sclerosed when the symptoms appear and that, when they are, the sclerosis might be looked on as evidence of the importance of the internal secretion of the testicles for the normal regulation of the circulatory apparatus and for the welfare of the general metabolism.

According to another opinion, recently expressed, the symptoms under discussion, though dependent on anomalies of internal secretion, owe their origin not to changes in the functions of the testicles alone, but, in addition, to alterations in the activities of other related glands, notably the prostate. It seems to be undeniable that some functional connection between the prostate and the testicles exists. Paul's studies[3] indicate that the enlargement of the prostate in advanced life is a retrogressive process, perhaps comparable to the chronic atrophic or inflammatory change in the female breast at the menopause. It is conceivable that further study may prove that the symptoms so often presented by men in their early sixties are due to polyglandular insufficiency.

Fascinating as these several hypotheses are, sober-minded medical men will, until evidence of validity is compelling, refrain from too ready acceptance of any one of them. Such hypotheses are, however, valuable as stimuli to more exact observation and to the extension of experimental inquiry; it is, accordingly, worth while occasionally to review the opinions put forward and the work which is being done in connection with so interesting a matter as the male climacteric.

THE ETIOLOGY OF BERIBERI

So many observations have been reported of late favoring the belief that beriberi is caused by a dietary insufficiency, that this conclusion is now apparently well established. In a recent contribution to the subject, Fraser and Stanton[1] not only have furnished additional evidence toward this view, but have carried the investigation of the dietary factor peculiarly lacking to a point previously unattained.

The employment of 300 native laborers in the construction of a road through virgin Malayan jungle offered an unusually favorable opportunity for their work. By properly examining all candidates for employment it was possible to exclude with a presumption of certainty men already suffering from the disease; and regulation of all sanitary conditions precluded the possibility that these might influence the results. The laborers so circumstanced were divided into two equal parties, and housed some distance apart. One section was then fed on polished rice as the staple article of diet, the other on rice which had been parboiled before husking. The latter grain differed from the former in the preservation of a great part of the subpericarpal layers, which are removed almost wholly by the more usual methods of polishing. Of the two parties, the men fed on polished rice began to develop cases of beriberi in three months, without the appearance of any cases in the other section. Conditions were then reversed, and after a somewhat longer period, the party previously exempt began to suffer from the disease, without any cases originating in the control party. The influence of place and the possibility of communicability were tested by the transfer of groups of sufferers, with negative results.

The polished rice thus responsible for the human disease was then tested by feeding to fowls. Eijkman[2] and others had previously shown that by feeding chickens on such grain it was possible to produce in them an affection very closely resembling human beriberi, both clinically and anatomically. Basing their experiments on this, Fraser and Stanton were able to cause a peripheral neuritis almost at will. It was found that the polished grain invariably caused the disease in a large proportion of the fowls if fed to them for a sufficient time. Substitution of parboiled rice, and the addition to the polished rice of the parts removed in polishing, served to protect the animals. Attempts to extract a soluble poison from the polished grain were unsuccessful, but on the other hand the extraction of unpolished rice with alcohol destroyed its protective power. The clue so obtained was followed up, and Fraser and Stanton succeeded in isolating to a certain point the element essential for protection. In addition to being extracted by alcohol, it was dissolved by 0.3 per cent. hydrochloric acid. An important constituent so removed is phytin—a complex organic compound with a high percentage of phosphorus pentoxid. As the amount of phosphoric acid in the grain had been found to give an index to its power to prevent neuritis, it was first thought that this might be the desired constituent; but feeding experiments contradicted this view, while the extract after removal of the phytin was still effective.

Although it has not so far been absolutely proved that the peripheral neuritis of fowls is identical with beriberi, there is no good reason for the contrary belief, so that quite probably the results of Fraser and Stanton will be found directly transferable to the human disease. While they unfortunately did not succeed in the ultimate isolation of the essential dietary factor, they have apparently carried the problem much further along, and more investigation should soon clear up its last uncertainties.

Current Comment

THE GREAT LAKES AS A WATER-SUPPLY

A movement of significance to a vast population was inaugurated at the recent meeting of the Municipal Congress in Chicago in the action looking toward the preservation of the purity of the Great Lakes as the most available water-supply for the cities and towns along their borders. The Great Lakes Basin International Pure Water Association was there formed, including in its membership city health officers, sanitary engineers and others, from both sides of the Canadian border-line. Each of the eight states and the two Canadian provinces bordering on the lakes is to have two official delegates, one appointed by the governor of each state or province, and the other by the health authorities. A temporary organization was formed and officers selected. The organization will be made permanent, and permanent officers elected on the appointment of the official delegates as provided above. It is expected that the Lake Michigan Water Commission will be merged with this organization. Canada has begun agitation for laws controlling the discharge of sewage into the Great Lakes, and the present organization will make the movement international. The Lake Michigan Water Commission was formed in 1908 to study the pollution of Lake Michigan. This commission was composed of representatives of the United States Public Health and Marine-Hospital Service, the engineering department of the War Department and the state and municipal health authorities of the states surrounding Lake Michigan. Much valuable work was done by this commission in the study of the contamination of the lakes, and reports have been made from time to time. Largely as the result of this study, it has been found necessary by the cities along the lakes deriving their water-supply from this source to extend their intakes farther and farther from the shores to avoid pollution. Even this is found not to surmount the difficulty altogether, as with the increasing volume of sewage discharged into the lakes because of the rapid increase in population and temporary or accidental storm conditions affecting the lake currents, the pollution is found to extend farther and farther from the shore. Pollution from passing shipping has also been determined to be a source of contamination which must be taken into consideration. The present organization seeks to apply such study to conditions along the whole body of the Great Lakes and to promote such legislation as is necessary to preserve the purity of the water-supply. The question is of increasing importance to the people affected. Chicago found it necessary to build a drainage canal which has only partially, and perhaps only temporarily, overcome the difficulty for a portion of the city and is now engaged in constructing another canal to give relief to the southern section of the city in the Calumet region. Many other cities along the lakes have individually put forth efforts to overcome to some extent the pollution of their water-supply, but the question is not wholly a local one and is far from being settled. This new organization ought to aid in bringing the necessity for concerted action before all the people concerned, and will, no doubt, result in both state and national action by the two governments with the effect of preventing, in large measure, the continued pollution of this great source of urban water-supply.

SMALL-POX IN THE UNITED STATES IN 1910

The number of cases of small-pox in the United States reported to the United States Public Health and Marine-Hospital Service for the year 1910 was 30,352, with 415 deaths. Complete reports were furnished by twenty-seven states, only partial reports being received from the others on account of their having no vital statistics laws. The total number of cases occurring, therefore, was no doubt considerably more than the figures quoted. The light death-rate, however, indicates that the infection was mild, as it has been throughout the past ten or twelve years of its prevalence in the United States; and yet in some instances, for reasons not apparent, the disease assumed considerable virulence and the death-rate ran up to 50 per cent. of the cases, as in the instance of thirty-eight cases reported from a certain district in Michigan during the months of October, November and December, 1910. This merely emphasizes what is well known—that the disease may at any time assume a virulent form and in non-vaccinated communities work great havoc. Though the number of deaths (415) is small, it is too large to represent the sacrifice in one year to a wholly preventable disease. In this day of general preventive medical measures, the occurrence of over thirty thousand cases of small-pox, with the attendant deaths, is discreditable to the wisdom of the people among whom they occur. Failure to insist on the enforcement of a protective measure that has proved its effectiveness for almost a hundred years invites the reflection that even in as progressive a country as ours compulsory general vaccination may yet have to be adopted, as it has been in Germany, Japan, Cuba, Porto Rico and the Philippines. Protective vaccination against some other infectious diseases, as typhoid, cholera and plague, seems to be demonstrating its value, but has not yet reached the point of such absolute proof by repeated trial and voluminous statistics as in the case of small-pox. Failure to benefit by the application of this proved procedure probably tends to postpone the employment of other preventive or protective measures. Small-pox, the first of the infectious diseases in which successful preventive inoculations have been applied, should long ago have disappeared from the face of the earth, or at least from civilized communities.

SUDDEN DISASTER AND CONSTANT DISEASE

The nation has been shocked by another appalling disaster, this time in Pennsylvania. A dam built across a narrow gap between two hills to hold back a vast volume of water, suddenly gave way. The flood poured down the valley, carrying death and destruction with it. Reports indicate that from 40 to 50 lives were lost in a few minutes. A wave of sympathy swept over the country. Red Cross physicians and nurses hastened to the scene. Food, clothing, hospital supplies and money poured into the death-swept valley. Special trains loaded with supplies and men started for the town almost as soon as the news of the disaster was received. The State of Pennsylvania and the entire nation, if necessary, stood ready to relieve suffering and to save life, without regard to the cost in labor or money. All this is right; nor should it be otherwise. Yet how strange that our sympathies should be aroused to immediate and purposeful action by the loss of 50 lives in a sudden and unusual way, yet leave us callous and indifferent to the fate of thousands who die from preventable but familiar causes. A Johnstown flood, an Iroquois fire, a San Francisco earthquake, will convulse the world with horror, yet the death from preventable diseases of over 600,000 people in the United States each year excites little interest. The newspapers announce the Austin disaster with front page "stories" and enormous head-lines, yet the United States Census report for 1908 (the last one available) shows that in that year in Pennsylvania alone, 2,450 people died of typhoid, 1,920 of diphtheria, 8,703 of tuberculosis, and that 9,026 infants under 2 years of age died of infantile diarrhea, a total mortality of 22,099 from only four preventable diseases in only one state. So accustomed are we to these enormous losses through familiar diseases, that we accept them as a matter of course and as the inevitable lot of mankind. Yet each of these diseases is as preventable as was the Austin flood.

SANITARY CONDITIONS IN THE COUNTRY

It is well known that advances in public sanitation have been much more rapid and effective in cities than in rural districts. Surface privies, the ubiquitous fly, and the horse manure pile which is its chief breeding-place, all combine to maintain the prevalence of typhoid fever in rural districts on a practical equality with that of the cities in the same districts. Infantile diarrhea, dysentery and tuberculosis exist in the country to a degree seemingly out of proportion to the exposure to infected water and food supplies. Speaking generally, farm life perhaps deserves its reputation for health-giving qualities. In this respect it is potentially as nearly perfect as any reputed health resort. The conditions rendering country life unhealthful are such as could easily be overcome, and with far less expense to the individual than in the city. Sanitary privies are easily and cheaply constructed; kitchen garbage can be protected from flies at a nominal cost, and the chief breeding-places of the fly can be rendered inaccessible without great trouble. The two factors most essential to a betterment of conditions are a campaign of education in sanitary matters among the people themselves and a more efficient organization of the local sanitary police force of the rural districts. As an example worthy of emulation, the work undertaken a few years ago by the New York State Department of Health is to be commended. Since 1907 it has carried on a system of inspecting summer resorts to determine any existing insanitary conditions which might be detrimental to the health of guests and to arrange for the amelioration of such conditions. The work of inspection each year has been confined to summer hotels and boarding-houses having accommodations for more than twenty-five persons, which are not connected with municipal water-supply and sewerage systems. During 1909, 259 out of 307 such resorts were found to maintain unhealthful conditions. The fault was generally in connection with privies and sewage disposal, though unsatisfactory water-supplies, defective plumbing and manure piles came in for a share of the censure. The matter of improving the sanitary condition of these 259 resorts was taken up with their proprietors, and as a result 156 had their places in good order during the inspection of the summer just past, leaving 103 of the original 259 still open to criticism. A list of these insanitary resorts is printed in the *Monthly Bulletin*.[1] The name of the resort, its location and its specific sanitary inadequacies are all placed in tabulated form on the first page. As this publication enjoys a large circulation among the laity, this ought to be a most efficient way of influencing the proprietors of these places to remedy the evil conditions. Practically every public library in the city of New York and throughout the state has the *Bulletin* in a conspicuous place on its reading-tables and in this way there is a "black list" of undesirable resorts at all times open for public inspection. Other states might profitably follow the example of New York. This work should also have a salutary effect in inducing non-resort rural communities to improve general sanitary conditions.

PRIZE CARTOONS

The Committee on Scientific Exhibit of the American Medical Association offered a prize of $200 for the best series of cartoons that should be exhibited at the Los Angeles session. The prize was awarded to Mr. Charles Batchelor, of Kansas City, who exhibited six cartoons. Although this was the first time such an offer had been made, the response was most gratifying; twenty-five contestants exhibited over 150 cartoons. The first of the series we published last week, and the second appears in this issue. It is the plan to print one each week hereafter until the series is completed. Arrangement has been made for the continuance for some time of other cartoons that will be of general medical interest.

Medical News

ILLINOIS

New Hospital.—The new Sparks Hospital, Carlyle, was formally dedicated, September 21. The hospital occupies site of the Lucas residence, to which an extensive addition has been built.

Personal.—Dr. John Haig, Le Roy, was injured recently by falling down a grain chute in an elevator.——Dr. Charles B. Dirks, Kankakee, has been appointed acting superintendent of the Elgin State Hospital.——Dr. Josiah M. Cody, Tremont, has been reappointed physician of Peoria County.

Chicago

Spinelli at Chicago.—Dr. Pier Giuseppe Spinelli, professor of gynecology of the Royal University of Naples, Italy, who has been visiting the Mayo Clinic at Rochester, Minn., is visiting in Chicago, and has been entertained by his countrymen and by the local medical association.

Personal.—Dr. and Mrs. Charles Adams, Dr. Vernon C. David, Dr. and Mrs. Glenn M. Hammon, Drs. Addison E. Elliott and Elmer L. Kenyon have sailed for Europe.——Dr. and Mrs. Arthur Geiger, Dr. and Mrs. L. L. McArthur, and Dr. Stephen C. De Veny have returned from Europe.——Dr. George J. Spencer, city physician, is reported to be seriously ill with pneumonia.

New German Hospital.—Plans have been approved for a new building to be occupied by the German Hospital of Chicago. The present building will be pulled down, and a new one erected. Mrs. Conrad Seipp has given $150,000 toward the improvement of the hospital in memory of her son and husband and this has been augmented by gifts from other friends of the institution, aggregating $100,000.

INDIANA

Asks for an Assistant.—Dr. J. P. Simonds, head of the pathological laboratory of the State Board of Health, Indianapolis, has asked for an additional pathologist, to be assigned to duty October 1.

Alumni Organize.—About forty alumni of the Kentucky School of Medicine held a meeting at the Denison Hotel, Indianapolis, during the meeting of the State Association, and formed a permanent organization. Dr. James B. Duncan, of Bedford, Ind., was elected president, Dr. Thomas C. Kennedy, of Indianapolis, secretary, and Dr. Daniel C. Peters, of Greentown, treasurer.

Defense Fund for Physicians.—The creation of a defense fund for the legal protection of physicians who are made the victims for suits for alleged malpractice was the most important matter before the house of delegates of the State Medical Association. The report of the committee as adopted provides that 75 cents should be set aside from the annual dues of each member for the defense fund. This will bring in about $1,800 a year.

Personal.—Dr. William W. Kemper, Muncie, has given up the practice of medicine and has moved to his farm near Lancaster, Ohio, where he will engage in agricultural pursuits.——Dr. Victor V. Bacon, Michigan City, secretary of the local board of health, is about to leave Michigan City and settle in Spokane, on account of the health of Mrs. Bacon.——Dr. Asa W. Brown, health officer of Bluffton, has resigned.——The condition of Dr. Adoniram J. Banker, Columbus, who is seriously ill at a sanatorium in Indianapolis, is reported to be improved.

State Society Meeting.—The Indiana State Medical Association met in annual session at Indianapolis, September 27, 28, 29. More than 700 physicians registered at the meeting and a medical achievement banquet was given on the night of September 28. This banquet was notable on account of the fact, although there were several thousand present, yet hundreds were turned away for lack of room. The principal speaker was Dr. Harvey W. Wiley, who spoke on "The Public Health Our Greatest Asset." Indianapolis was chosen as the meeting place for next year, and the following officers were elected: president, Dr. William F. Howatt, Hammond, Ind.; vice-presidents, Drs. George E. Keiper, Lafayette, Bader S. Hunt, Winchester, Dr. Thomas F. Spink, Washington, and secretary, Dr. Charles N. Combs, Terre Haute (reelected); delegates to the American Medical Association, Drs. J. Rilus Eastman, Indianapolis, and Edwin Walker, Evansville; and alternates, Dr. William R. Davidson, Evansville, and Dr. George R. Osborn, Laporte. Dr. Osborne also was elected as the tenth district member of the board of councilors, this being the only change in the board. A resolution was adopted by the house of delegates creating a new section of the association. It will be known as the eye, ear, nose and throat section, and it will hold sessions at the meeting next year.

---

[1] Monthly Bulletin N. Y. State Department of Health, August, 1911

MARYLAND

Monument for Revolutionary Surgeon.—The grave of Assistant Surgeon Richard Waters of the Maryland Line Continetal Army at Laytonsville is to be marked by a monument. The ceremony will take place October 7, and will be under the charge of the Daughters of the American Revolution.

Hospital to be Opened.—The new Havre de Grace Hospital will be formally opened, October 16. The new institution is located in the old Baker Home, which has been remodeled at the cost of $12,000, and later a $6,000 addition will be built. Among the directors are Drs. James Lee Hopkins, secretary, and Frederick W. Steiner.

Personal.—Dr. Charles L. Mattfeldt has been elected president of the Catonsville Country Club.——Dr. Harry F. Shipley, Granite, who was recently a patient at the University Hospital, Baltimore, has recovered and returned home.——Rt. Rev. Luther B. Wilson, M.D., has recovered from his recent attack of African fever and has gone to Syracuse, N. Y.

Baltimore

To and from Europe.—Drs. William M. Dabney and George H. Everhartd have sailed for Europe, and Drs. Emil Novak, Anton G. Rytina, John Ruhräh and William C. Baer have returned from abroad.

Kelly Recovered.—Dr. Howard A. Kelly left Rochester, Minn., September 21 for his camp at Indian Point, 150 miles northwest of Toronto, Ont., and he expects to return to Baltimore about the end of October.

New Department in the University.—A new department is to be inaugurated in Johns Hopkins Hospital this fall, namely that of art as applied to medicine. It will be under the charge of the associate professor Max Broedel, who has had charge of the medical illustration department of the hospital for several years. Two classes are to be provided for medical students and artists. The purpose of the department is "to bridge over the gap existing between art and medicine, and to train a new generation of artists to illustrate medical journals and books in the future, and to spare them the years of trial and disappointment of their self-taught predecessors."

Personal.—Drs. Mary Sherwood and Joseph E. Gichner have been reappointed members of the Public Bath Commission.——Dr. Christian Deetjen has recovered from the operation which he underwent at St. Agnes' Hospital in June last for *x*-ray burns. Fourteen of these spots were removed from the hands of Dr. Deetjen and replaced by fresh skin grafts from the thighs of the patient.——Dr. Willis D. Gatch has resigned from the staff of Johns Hopkins Hospital to become professor of surgery in the Indianapolis Medical College.——Dr. J. P. Pratt has been made assistant resident surgeon in Johns Hopkins Hospital, and Dr. W. E. Dandy has been appointed assistant to Dr. Harvey W. Cushing.

MICHIGAN

Personal.—Dr. Herman H. Ruonavaara, Calumet, has given up general practice in order to study through the winter.——Drs. John E. Handy, Caro, and John G. Maurer, Watrousville, sustained cuts and bruises in an automobile accident, near Watrousville, September 19.—Drs. John H. Kellogg and James T. Case, Battle Creek, have sailed for Europe.

Physicians Honor Carstens.—A complimentary banquet was given to Dr. John Henry Carstens of Detroit, by his colleagues, September 27, in honor of his service in contributions to the medical profession. Dr. Henry O. Walker, Charles G. Jennings and Eugene Smith acted as toastmasters. The toasts took up various characteristics of Dr. Carstens. Dr. Theodore A. McGraw spoke of him as a student, practitioner and surgeon. Dr. Colonel B. Burr, Flint, president of the state medical society, spoke of Dr. Carstens' service to the profession of the state of Michigan. Dr. Joseph L. Hudson, Detroit, one of the managers of the Harper Hospital, eulogized Dr. Carstens as a hospital chief and citizen. Dr. Ernest L. Shurly, Detroit, spoke of Dr. Carstens as a friend and colleague, and Walter Hume Sawyer, Hillsdale, regent of University of Michigan, has as his subject, "Specialties." Governor Osborn paid a high tribute to the entire medical profession, and closed by saying: "Here to-night you are recognizing a master among you and that proves that you are all masters in your profession."

MISSOURI

Applicants for License Must Have Clear Record.—The State Board of Health has instituted a system of checking the courses in medical colleges taken by applicants for license to practice. Whenever it appears that any one of the courses has been taken in a college not on the accredited list the applicant will be denied the right to take the examination.

Dr. Wheeler Sustained.—The Hospital and Health Board of Kansas City has exonerated the health commissioner, Dr. Walter S. Wheeler of all charges brought against him by the milk producers' association. The board praised the work of Dr. Wheeler; it declared there had been no favoritism in dealing with dairymen, and that the milk-supply of the city was much better than it was before the campaign which Dr. Wheeler started. The investigation was ordered by the mayor on complaints brought by the milk producers' association.

St. Louis

Local Schools Disqualified.—The daily papers of October 1 and 2 announce that Barnes University and the College of Physicians and Surgeons, which are preparing to consolidate, were stricken off the list of approved schools by the State Board of Health, September 30, on account of numerous deficiencies. Inadequacies in methods of teaching were disclosed, and the laboratories of both are said to have been found defective, and the records so incompletely kept as to give no positive evidence as to the completeness of the course their students have been receiving.

Wiley Addresses City Club.—Dr. Harvey W. Wiley, chief of the Bureau ot Chemistry, was entertained at luncheon by the City Club, September 27. About 400 members attended and listened with rare appreciation to the address Dr. Wiley delivered on "Public Health, the Nation's Greatest Asset." He declared that the most precious thing in St. Louis was its citizenship. He said the average human adult costs his parents and the state $12,000 and the annual loss through deaths from preventable diseases would far out-total the capital of all the banks and public utilities in the city. He made a strong plea for the conservation of the health of the people.

NEBRASKA

Asylum Changes.—The governor of Nebraska announced September 28 that he would retain Dr. Benjamin F. Williams as successor to the late Dr. John T. Hay, superintendent of the Nebraska Hospital for the Insane, Lincoln, until Jan. 1, 1912, and that he will then appoint Dr. Gustav W. Dishong, superintendent of the institution.

NEW YORK

Personal.—Dr. Arthur E. Soper of Northport has been appointed junior physician at the Manhattan State Hospital.——Dr. Fred M. Meader, Syracuse, has succeeded Dr. Willis W. Waite, as bacteriologist of Syracuse.

New Pavilions for Tuberculosis Patients.—Two new pavilions were opened on September 26 at the State Hospital for Incipient Tuberculosis at Raybrook, on which occasion bronze tablets were unveiled in each pavilion. That in one of the pavilions commemorates the work of Dr. John H. Pryor of Buffalo and that in the other that of the late Dr. Willis G. MacDonald of Albany. The cost of these pavilions was about $200,000 and doubles the capacity of the institution, making it possible to care for 600 patients annually. A new home for the help to cost $65,000 is also being erected on the grounds.

New York City

Personal.—Dr. Thomas E. Satterthwaite has returned from Europe.——Dr. Walter Lester Carr has been elected president of the American Pediatric Society, and not Dr. Augustus Caille, as erroneously stated in *The Journal* of July 1.——Drs. Delmer H. Durgin, Richard G. Eaton and Joseph H. Shufelter have been appointed junior physicians of the King's Park State Hospital.

Harvey Society Lectures.—The Harvey Society announces that during October the following lectures will be given at the Acadmey of Medicine at 8:30 p. m.: October 7—"Local Specific Therapy of Infections," by Dr. Simon Flexner of New York; October 14—"Chemical Structure of the Cell," by Prof. Albrecht Kossel, Heidelberg; October 28—"Anesthesia," by Prof. Max Verworn, Bonn, Germany.

Diseases in Books.—Dr. Samuel D. Hubbard of the Board of Health in speaking before the New York Library Association warned against the dangers of spreading disease through the circulating library. He thought that every library should have a corps of inspectors whose duty should be subject to a rigid examination of all books returned. All those which bore suspicious-looking marks should be destroyed and all books should be disinfected at frequent intervals.

To Study Tropical Diseases.—The New York Post-Graduate Medical School and Hospital is preparing to send out an expedition next spring for the purpose of studying tropical diseases. A special fund of $15,000 for this purpose has been donated by Col. Robert M. Thompson of this city and John H. McFadden of Philadelphia. Capt. Joseph F. Siler, M.C., U. S. A., lecturer on tropical diseases, will have charge of the expedition and is actively engaged in the preliminary work.

The Common Drinking Cup Prohibited.—The new provision of the Sanitary Code of the Board of Health reads: The use of a common drinking cup or receptacle for the drinking of water in any public place or in any public institution, hotel, theater, factory, public hall, or public school, or in any railroad station or ferry house in the city of New York, or the furnishing of such common drinking cup or receptacle for use in such place is hereby prohibited. . . . The same to take effect on and after the first day of October, 1911.

Low Infant Mortality.—The department of health announces that for the week ended September 23, there were 324 deaths from all causes of infants under 1 year of age in Greater New York as compared with 343 for the same period in 1910. From January 1 to September 23 there have been 11,442 deaths of infants under 1 year of age, as compared with 12,603 for the same period of 1910. This is a reduction in the number of deaths of 1,161, so that the agencies which started out early in the year to save 1,000 infants may be considered as having succeeded in their effort.

Will Continue Pure Food Fight.—The Pure Food and Drug Department of the National Civic Federation, of which Seth Low is president, held two meetings in the rooms of the New York Board of Trade on October 2. At this time the following questions were up for consideration: "What is the Actual Situation in This Country with Reference to the Enforcement of the Federal and State Pure Food and Drug Laws?" and "What Legislation and What Changes in Administration will More Effectually Safeguard the People Against Alleged Food and Drug Adulterators, Misbranders and Short-Weighers?" Dr. Thomas Darlington, New York City, Dr. Harvey W. Wiley, Washington, D. C., and Dr. William C. Woodward, Washington, D. C., were speakers on this occasion.

OHIO

Health Boards to Convene.—The thirty-first conference of the Ohio State Board of Health with representatives of local health boards will be held at the Sinton Hotel, Cincinnati, October 19 and 20.

Personal.—Dr. Samuel S. Thorn, for more than fifty years a surgeon of Toledo, was the guest of honor at a banquet, September 22, tendered by the Toledo Academy of Medicine, on the occasion of his eightieth birthday anniversary.——Dr. W. W. Peter, Toledo, sails this month for China as a medical missionary of the Evangelical church.——Dr. and Mrs. Dudley P. Allen, Cleveland, have reached San Francisco on their return from the Orient.

Antituberculosis Society Election.—At the annual meeting of the Ohio Society for the Prevention of Tuberculosis, held in Columbus, September 9, the following officers were elected: Dr. John H. Lowman, Cleveland, president; Drs. Walter W. Brand, Toledo, and Frank Warner, Columbus, vice-presidents; Dr. Henry Baldwin, Springfield, secretary; and Foster Copeland, Columbus, treasurer. The following physicians were elected members of the board of directors: Drs. Robert H. Bishop, Cleveland; Charles O. Probst, Columbus; Edward V. Hug, Lorain, and Harry E. Welch, Youngstown; John S. Beck, Dayton; Clayton B. Conwell, Cincinnati; Ralph P. Daniells, Toledo; Horace Bonner, Dayton; Otto P. Geier, Cincinnati; Esther M. Tyrrell, Canton, and James B. Poling, Lima.

PENNSYLVANIA

Personal.—Dr. A. Chester Wolfe, Ridley Park, sustained a fracture of two ribs, and severe lacerations and contusions in an automobile accident, September 23.——Dr. Daniel P. Maddox, chief of the surgical staff at the Crozier Hospital, Chester, who suffered from a fracture of the skull, while alighting from an automobile, September 26, is reported to be doing well.

State Society Meeting.—The sixty-first annual session of the Medical Society of the State of Pennsylvania was held in Harrisburg, September 25-28. At the meeting of the House of Delegates, September 27, the following officers were elected: president, Dr. James Tyson, Philadelphia; vice-presidents, Drs. Hugh Hamilton, Harrisburg; Walter F. Lathrop, Hazelton; George W. Kehl, Reading, and Howard C. Frontz, Huntingdon; secretary, Dr. Cyrus L. Stevens, Athens (reelected); treasurer, Dr. George W. Wagoner, Johnstown; delegates to the American Medical Association, Drs. George W. Guthrie, Wilkes-Barre; Theodore B. Appel, Lancaster, and John B. Lowman, Johnstown; alternates, Drs. Wilmer Krusen, Philadelphia; George D. Nutt, Williamsport; George R. S. Corson, Pottsville; Americus R. Allen, Carlisle, and Henry D. Jump, Philadelphia: A. Wayne Baugh, Paoli; George G. Harman, Huntingdon; John C. Gilland, Greencastle; Lowell M. Gates, Scranton, and Philip Y. Eisenberg, Norristown. On September 28, the following trustees were elected: Drs. William T. Staples, West Chester; Frederick L. Van Sickle, Olyphant, and Dr. Alem P. Hull, Montgomery. At the meeting of the house of delegates on September 28, the following resolution endorsing Dr. Harvey W. Wiley was passed: "Resolved, That the Medical Society of the State of *Pennsylvania* commends the work of Dr. Harvey W. Wiley as chief of the Bureau of Chemistry of the Department of Agriculture for his earnest efforts to enforce the pure food and dairy laws of the United States." Scranton was selected as the place of meeting for 1912.

Philadelphia

Personal.—The following physicians have returned from Europe: Drs. James M. Anders, Henry K. Gaskill, J. Nicholas Mitchell and G. Oram Ring.——C. P. Decker sailed for Europe on September 30.

Medical Club Reception.—The first reception of the Medical Club of Philadelphia for the year was given at the Bellevue-Stratford Hotel, October 6, in honor of the recently elected professors of the University of Pennsylvania: Drs. Gwilym G. Davis, John B. Deaver, M. Howard Fussell, Milton B. Hartzell, Edward Martin, A. M. Pearce, A. H. Richards, Alfred Stengel and Alonzo E. Taylor.

Baby Hospitals Close.—The Chestnut Street Pier Hospital *and "The Babies Hospital" in the park* closed October 1. According to the report of the department of health, 10,000 babies and 6,000 mothers received attention of the physicians and nurses at the Chestnut Street Pier up to September 15. Babies received treatment and food, and the mothers were taught the care of infants and how to "modify" milk. The cost of this work was less than 7 cents a day per head.

WISCONSIN

Free Antityphoid Vaccine.—Dr. Mazyck P. Ravenel, head of the department of bacteriology in the State University of Madison, and director of the state laboratory, announces that beginning December 1, antityphoid vaccine will be supplied to physicians of the state free of charge.

Health Bulletins Planned.—The committee on hygiene of the University of Wisconsin plans to issue twelve bulletins during the academic year, for the benefit of the students, dealing with such subjects as the care of the feet, rest and exercise, the use of "patent medicines," and the care of the throat, mouth and teeth, etc.

Sanatorium Plans Approved.—The plans for the new Fond du Lac County Tuberculosis Sanatorium, as submitted by the board of control, were approved at a joint conference of the special county board committee, with Dr. Frisbie of the State Board of Control, and Miss Edyth L. M. Tate of the Wisconsin Antituberculosis Society.

State Convention to Meet.—At the annual meeting of the Wisconsin Antituberculosis Association to be held in Milwaukee, October 13, reports from twenty Wisconsin cities on the antituberculosis work in their respective districts will be grouped under the head of "A Bird's-Eye View of the Crusade." The chief speaker will be Dr. Richard C. Cabot, Boston.

Advocates Convalescent Farm.—The State Tuberculosis Commission is considering the purchase of a plot of ground 40 acres in extent, near Milwaukee, for market gardening. The raising of poultry and garden truck is considered by many members as the most feasible solution of the problem of securing work for patients who have suffered from tuberculosis, and have been discharged as apparently cured.

Personal.—Dr. Fernando C. Mock, Milwaukee, has been elected chancellor and Dr. John A. Winters, La Crosse, national sentry of the Yeomen of America.——Dr. John V. R. Lyman, Eau Claire, broke two ribs and sustained other serious injuries in a collision between his automobile and a street car, September 24.——Dr. Robert A. Kitto, Racine, who was seriously injured in an automobile accident, is reported to be convalescent.——Dr. Aart Van Westrienen, Kenosha, caught his left hand in the gearing of his automobile, September 23, being the only change in the board. A resolution was adopted by the house of delegates creating a new section of the association. It will be known as the eye, ear, nose and throat section, and it will hold sessions at the meeting next year.

MARYLAND

Monument for Revolutionary Surgeon.—The grave of Assistant Surgeon Richard Waters of the Maryland Line Continetal Army at Laytonsville is to be marked by a monument. The ceremony will take place October 7, and will be under the charge of the Daughters of the American Revolution.

Hospital to be Opened.—The new Havre de Grace Hospital will be formally opened, October 16. The new institution is located in the old Baker Home, which has been remodeled at the cost of $12,000, and later a $6,000 addition will be built. Among the directors are Drs. James Lee Hopkins, secretary, and Frederick W. Steiner.

Personal.—Dr. Charles L. Mattteldt has been elected president of the Catonsville Country Club.——Dr. Harry F. Shipley, Granite, who was recently a patient at the University Hospital, Baltimore, has recovered and returned home.——Rt. Rev. Luther B. Wilson, M.D., has recovered from his recent attack of African fever and has gone to Syracuse, N. Y.

Baltimore

To and from Europe.—Drs. William M. Dabney and George H. Everhartd have sailed for Europe, and Drs. Emil Novak, Anton G. Rytina, John Ruhräh and William C. Baer have returned from abroad.

Kelly Recovered.—Dr. Howard A. Kelly left Rochester, Minn., September 21 for his camp at Indian Point, 150 miles northwest of Toronto, Ont., and he expects to return to Baltimore about the end of October.

New Department in the University.—A new department is to be inaugurated in Johns Hopkins Hospital this fall, namely that of art as applied to medicine. It will be under the charge of the associate professor Max Broedel, who has had charge of the medical illustration department of the hospital for several years. Two classes are to be provided for medical students and artists. The purpose of the department is "to bridge over the gap existing between art and medicine, and to train a new generation of artists to illustrate medical journals and books in the future, and to spare them the years of trial and disappointment of their self-taught predecessors."

Personal.—Drs. Mary Sherwood and Joseph E. Gichner have been reappointed members of the Public Bath Commission.——Dr. Christian Deetjen has recovered from the operation which he underwent at St. Agnes' Hospital in June last for *x*-ray burns. Fourteen of these spots were removed from the hands of Dr. Deetjen and replaced by fresh skin grafts from the thighs of the patient.——Dr. Willis D. Gatch has resigned from the staff of Johns Hopkins Hospital to become professor of surgery in the Indianapolis Medical College.——Dr. J. P. Pratt has been made assistant resident surgeon in Johns Hopkins Hospital, and Dr. W. E. Dandy has been appointed assistant to Dr. Harvey W. Cushing.

MICHIGAN

Personal.—Dr. Herman H. Ruonavaara, Calumet, has given up general practice in order to study through the winter.——Drs. John E. Handy, Caro, and John G. Maurer, Watrousville, sustained cuts and bruises in an automobile accident, near Watrousville, September 19.—Drs. John H. Kellogg and James T. Case, Battle Creek, have sailed for Europe.

Physicians Honor Carstens.—A complimentary banquet was given to Dr. John Henry Carstens of Detroit, by his colleagues, September 27, in honor of his service in contributions to the medical profession. Dr. Henry O. Walker, Charles G. Jennings and Eugene Smith acted as toastmasters. The toasts took up various characteristics of Dr. Carstens. Dr. Theodore A. McGraw spoke of him as a student, practitioner and surgeon. Dr. Colonel B. Burr, Flint, president of the state medical society, spoke of Dr. Carstens' service to the profession of the state of Michigan. Dr. Joseph L. Hudson, Detroit, one of the managers of the Harper Hospital, eulogized Dr. Carstens as a hospital chief and citizen. Dr. Ernest L. Shurly, Detroit, spoke of Dr. Carstens as a friend and colleague, and Walter Hume Sawyer, Hillsdale, regent of University of Michigan, has as his subject, "Specialties." Governor Osborn paid a high tribute to the entire medical profession, and closed by saying: "Here to-night you are recognizing a master among you and that proves that you are all masters in your profession."

MISSOURI

Applicants for License Must Have Clear Record.—The State Board of Health has instituted a system of checking the courses in medical colleges taken by applicants for license to practice. Whenever it appears that any one of the courses has been taken in a college not on the accredited list the applicant will be denied the right to take the examination.

Dr. Wheeler Sustained.—The Hospital and Health Board of Kansas City has exonerated the health commissioner, Dr. Walter S. Wheeler of all charges brought against him by the milk producers' association. The board praised the work of Dr. Wheeler; it declared there had been no favoritism in dealing with dairymen, and that the milk-supply of the city was much better than it was before the campaign which Dr. Wheeler started. The investigation was ordered by the mayor on complaints brought by the milk producers' association.

St. Louis

Local Schools Disqualified.—The daily papers of October 1 and 2 announce that Barnes University and the College of Physicians and Surgeons, which are preparing to consolidate, were stricken off the list of approved schools by the State Board of Health, September 30, on account of numerous deficiencies. Inadequacies in methods of teaching were disclosed, and the laboratories of both are said to have been found defective, and the records so incompletely kept as to give no positive evidence as to the completeness of the course their students have been receiving.

Wiley Addresses City Club.—Dr. Harvey W. Wiley, chief of the Bureau of Chemistry, was entertained at luncheon by the City Club, September 27. About 400 members attended and listened with rare appreciation to the address Dr. Wiley delivered on "Public Health, the Nation's Greatest Asset." He declared that the most precious thing in St. Louis was its citizenship. He said the average human adult costs his parents and the state $12,000 and the annual loss through deaths from preventable diseases would far out-total the capital of all the banks and public utilities in the city. He made a strong plea for the conservation of the health of the people.

NEBRASKA

Asylum Changes.—The governor of Nebraska announced September 28 that he would retain Dr. Benjamin F. Williams as successor to the late Dr. John T. Hay, superintendent of the Nebraska Hospital for the Insane, Lincoln, until Jan. 1, 1912, and that he will then appoint Dr. Gustav W. Dishong, superintendent of the institution.

NEW YORK

Personal.—Dr. Arthur E. Soper of Northport has been appointed junior physician at the Manhattan State Hospital.——Dr. Fred M. Meader, Syracuse, has succeeded Dr. Willis W. Waite, as bacteriologist of Syracuse.

New Pavilions for Tuberculosis Patients.—Two new pavilions were opened on September 26 at the State Hospital for Incipient Tuberculosis at Raybrook, on which occasion bronze tablets were unveiled in each pavilion. That in one of the pavilions commemorates the work of Dr. John H. Pryor of Buffalo and that in the other that of the late Dr. Willis G. MacDonald of Albany. The cost of these pavilions was about $200,000 and doubles the capacity of the institution, making it possible to care for 600 patients annually. A new home for the help to cost $65,000 is also being erected on the grounds.

New York City

Personal.—Dr. Thomas E. Satterthwaite has returned from Europe.——Dr. Walter Lester Carr has been elected president of the American Pediatric Society, and not Dr. Augustus Caille, as erroneously stated in The Journal of July 1.——Drs. Delmer H. Durgin, Richard G. Eaton and Joseph H. Shufelter have been appointed junior physicians of the King's Park State Hospital.

Harvey Society Lectures.—The Harvey Society announces that during October the following lectures will be given at the Acadmey of Medicine at 8:30 p. m.: October 7—"Local Specific Therapy of Infections," by Dr. Simon Flexner of New York; October 14—"Chemical Structure of the Cell," by Prof. Albrecht Kossel, Heidelberg; October 28—"Anesthesia," by Prof. Max Verworn, Bonn, Germany.

Diseases in Books.—Dr. Samuel D. Hubbard of the Board of Health in speaking before the New York Library Association warned against the dangers of spreading disease through the circulating library. He thought that every library should have a corps of inspectors whose duty should be subject to a rigid examination of all books returned. All those which bore suspicious-looking marks should be destroyed and all books should be disinfected at frequent intervals.

To Study Tropical Diseases.—The New York Post-Graduate Medical School and Hospital is preparing to send out an expedition next spring for the purpose of studying tropical diseases. A special fund of $15,000 for this purpose has been donated by Col. Robert M. Thompson of this city and John H. McFadden of Philadelphia. Capt. Joseph F. Siler, M.C., U. S. A., lecturer on tropical diseases, will have charge of the expedition and is actively engaged in the preliminary work.

The Common Drinking Cup Prohibited.—The new provision of the Sanitary Code of the Board of Health reads: The use of a common drinking cup or receptacle for the drinking of water in any public place or in any public institution, hotel, theater, factory, public hall, or public school, or in any railroad station or ferry house in the city of New York, or the furnishing of such common drinking cup or receptacle for use in such place is hereby prohibited. . . . The same to take effect on and after the first day of October, 1911.

Low Infant Mortality.—The department of health announces that for the week ended September 23, there were 324 deaths from all causes of infants under 1 year of age in Greater New York as compared with 343 for the same period in 1910. From January 1 to September 23 there have been 11,442 deaths of infants under 1 year of age, as compared with 12,603 for the same period of 1910. This is a reduction in the number of deaths of 1,161, so that the agencies which started out early in the year to save 1,000 infants may be considered as having succeeded in their effort.

Will Continue Pure Food Fight.—The Pure Food and Drug Department of the National Civic Federation, of which Seth Low is president, held two meetings in the rooms of the New York Board of Trade on October 2. At this time the following questions were up for consideration: "What is the Actual Situation in This Country with Reference to the Enforcement of the Federal and State Pure Food and Drug Laws?" and "What Legislation and What Changes in Administration will More Effectually Safeguard the People Against Alleged Food and Drug Adulterators, Misbranders and Short-Weighers?" Dr. Thomas Darlington, New York City, Dr. Harvey W. Wiley, Washington, D. C., and Dr. William C. Woodward, Washington, D. C., were speakers on this occasion.

OHIO

Health Boards to Convene.—The thirty-first conference of the Ohio State Board of Health with representatives of local health boards will be held at the Sinton Hotel, Cincinnati, October 19 and 20.

Personal.—Dr. Samuel S. Thorn, for more than fifty years a surgeon of Toledo, was the guest of honor at a banquet, September 22, tendered by the Toledo Academy of Medicine, on the occasion of his eightieth birthday anniversary.——Dr. W. W. Peter, Toledo, sails this month for China as a medical missionary of the Evangelical church.——Dr. and Mrs. Dudley P. Allen, Cleveland, have reached San Francisco on their return from the Orient.

Antituberculosis Society Election.—At the annual meeting of the Ohio Society for the Prevention of Tuberculosis, held in Columbus, September 9, the following officers were elected: Dr. John H. Lowman, Cleveland, president; Drs. Walter W. Brand, Toledo, and Frank Warner, Columbus, vice-presidents; Dr. Henry Baldwin, Springfield, secretary; and Foster Copeland, Columbus, treasurer. The following physicians were elected members of the board of directors: Drs. Robert H. Bishop, Cleveland; Charles O. Probst, Columbus; Edward V. Hug, Lorain, and Harry E. Welch, Youngstown; John S. Beck, Dayton; Clayton B. Conwell, Cincinnati; Ralph P. Daniells, Toledo; Horace Bonner, Dayton; Otto P. Geier, Cincinnati; Esther M. Tyrrell, Canton, and James B. Poling, Lima.

PENNSYLVANIA

Personal.—Dr. A. Chester Wolfe, Ridley Park, sustained a fracture of two ribs, and severe lacerations and contusions in an automobile accident, September 23.——Dr. Daniel P. Maddox, chief of the surgical staff at the Crozier Hospital, Chester, who suffered from a fracture of the skull, while alighting from an automobile, September 26, is reported to be doing well.

State Society Meeting.—The sixty-first annual session of the Medical Society of the State of Pennsylvania was held in Harrisburg, September 25-28. At the meeting of the House of Delegates, September 27, the following officers were elected: president, Dr. James Tyson, Philadelphia; vice-presidents, Drs. Hugh Hamilton, Harrisburg; Walter F. Lathrop, Hazelton; George W. Kehl, Reading, and Howard C. Frontz, Huntingdon; secretary, Dr. Cyrus L. Stevens, Athens (reelected); treasurer, Dr. George W. Wagoner, Johnstown; delegates to the American Medical Association, Drs. George W. Guthrie, Wilkes-Barre; Theodore B. Appel, Lancaster, and John B. Lowman, Johnstown; alternates, Drs. Wilmer Krusen, Philadelphia; George D. Nutt, Williamsport; George R. S. Corson, Pottsville; Americus R. Allen, Carlisle, and Henry D. Jump, Philadelphia; A. Wayne Baugh, Paoli; George G. Harman, Huntingdon; John C. Gilland, Greencastle; Lowell M. Gates, Scranton, and Philip Y. Eisenberg, Norristown. On September 28, the following trustees were elected: Drs. William T. Staples, West Chester; Frederick L. Van Sickle, Olyphant, and Dr. Alem P. Hull, Montgomery. At the meeting of the house of delegates on September 28, the following resolution endorsing Dr. Harvey W. Wiley was passed: "Resolved, That the Medical Society of the State of Pennsylvania commends the work of Dr. Harvey W. Wiley as chief of the Bureau of Chemistry of the Department of Agriculture for his earnest efforts to enforce the pure food and dairy laws of the United States." Scranton was selected as the place of meeting for 1912.

Philadelphia

Personal.—The following physicians have returned from Europe: Drs. James M. Anders, Henry K. Gaskill, J. Nicholas Mitchell and G. Oram Ring.——C. P. Decker sailed for Europe on September 30.

Medical Club Reception.—The first reception of the Medical Club of Philadelphia for the year was given at the Bellevue-Stratford Hotel, October 6, in honor of the recently elected professors of the University of Pennsylvania: Drs. Gwilym G. Davis, John B. Deaver, M. Howard Fussell, Milton B. Hartzell, Edward Martin, A. M. Pearce, A. H. Richards, Alfred Stengel and Alonzo E. Taylor.

Baby Hospitals Close.—The Chestnut Street Pier Hospital and "The Babies Hospital" in the park closed October 1. According to the report of the department of health, 10,000 babies and 6,000 mothers received attention of the physicians and nurses at the Chestnut Street Pier up to September 15. Babies received treatment and food, and the mothers were taught the care of infants and how to "modify" milk. The cost of this work was less than 7 cents a day per head.

WISCONSIN

Free Antityphoid Vaccine.—Dr. Mazyck P. Ravenel, head of the department of bacteriology in the State University of Madison, and director of the state laboratory, announces that beginning December 1, antityphoid vaccine will be supplied to physicians of the state free of charge.

Health Bulletins Planned.—The committee on hygiene of the University of Wisconsin plans to issue twelve bulletins during the academic year, for the benefit of the students, dealing with such subjects as the care of the feet, rest and exercise, the use of "patent medicines," and the care of the throat, mouth and teeth, etc.

Sanatorium Plans Approved.—The plans for the new Fond du Lac County Tuberculosis Sanatorium, as submitted by the board of control, were approved at a joint conference of the special county board committee, with Dr. Frisbie of the State Board of Control, and Miss Edyth L. M. Tate of the Wisconsin Antituberculosis Society.

State Convention to Meet.—At the annual meeting of the Wisconsin Antituberculosis Association to be held in Milwaukee, October 13, reports from twenty Wisconsin cities on the antituberculosis work in their respective districts will be grouped under the head of "A Bird's-Eye View of the Crusade." The chief speaker will be Dr. Richard C. Cabot, Boston.

Advocates Convalescent Farm.—The State Tuberculosis Commission is considering the purchase of a plot of ground 40 acres in extent, near Milwaukee, for market gardening. The raising of poultry and garden truck is considered by many members as the most feasible solution of the problem of securing work for patients who have suffered from tuberculosis, and have been discharged as apparently cured.

Personal.—Dr. Fernando C. Mock, Milwaukee, has been elected chancellor and Dr. John A. Winters, La Crosse, national sentry of the Yeomen of America.——Dr. John V. R. Lyman, Eau Claire, broke two ribs and sustained other serious injuries in a collision between his automobile and a street car, September 24.——Dr. Robert A. Kitto, Racine, who was seriously injured in an automobile accident, is reported to be convalescent.——Dr. Aart Van Westrienen, Kenosha, caught his left hand in the gearing of his automobile, September 23, and fractured and lacerated the fingers of the hand.——Dr. Warner B. Strong, Health Commissioner of Waukesha, has resigned and will remove to St. Martins.——Dr. David W. Ashum, Eau Claire, who is ill at the Sacred Heart Hospital, is reported to be convalescing.

GENERAL NEWS

Leper Deported.—Acieto Paleby, a Philippino leper, who has been held in isolation in Washington for six months, was deported on the transport *Dixon* which sailed from Seattle for Manila, September 15.

District Association Meeting.—The fall meeting of the Iowa and Illinois Central District Medical Association will be held in the Harms Hotel, Rock Island, Ill., October 12, under the presidency of Dr. Herbert M. Decker, Davenport.

Army Medical School Opens.—The Army Medical School, Washington, opened for its regular term, October 2. Fifty-eight candidates for appointment for the medical corps, who have successfully passed the examination, reported for duty.

Health Experts' Conference.—The annual conference of the New York State Department of Health will be held in New York City, October 25. Health departments of adjoining states will be represented by delegates. E. J. Lederer, Health Commissioner of New York City, will speak on the "Activity of the Health Department."

Health Lectures in Canal Zone.—A series of health lectures is being given in Colon, under the auspices of the Cristobal Women's Club, and the success of the series has been so marked that it is probable that similar lectures will be given in the other American villages in the zone. The first lecture was on tuberculosis and was illustrated; the second was on the typhoid germ and the danger of the house fly.

National Conservation Congress.—At the third meeting of the National Conservation Congress held at Kansas City, September 26, the congress adopted resolutions approving the work of the United States Government in improving sanitary conditions and in lowering the death-rates of Cuba, the Philippine Islands and the Canal Zone; expressing satisfaction that in 1911 the national government, through its wise provisions for the maneuver division of the United States Army operating in Western Texas, demonstrated that the achievements in health and life security found possible in Cuba, the Philippine Islands and the Canal Zone, are possible with Americans on American soil; calling on our national, state and municipal governments to accomplish the same results for the people of the United States; calling attention to the fact that the national government, in the Canal Zone of Panama, has demonstrated that Caucasians, properly directed, can work in the tropics and semi-tropics without loss of efficiency; expressing the opinion that this is one of the monumental discoveries of the age; endorsing the efforts of the hookworm commission and all other efforts, governmental and extra-governmental, for increasing human efficiency through promotion of physical welfare, and calling on our governments—national, state and municipal—to increase their activities along these lines; favoring a child welfare bureau as a part of the health department of the national government, and each state and municipal government endorsing the plan of bringing together, under one direction, the various human health activities of the United States Government as a coordinated branch of its administrative work, divorced from the impediment of being a part of other administrative work of an entirely different character and conducted for entirely different purposes—this in order that the efficiency of the service may be increased to a point in some degree commensurate with its importance; protesting against the present rank neglect of health and life security, and of work for physical efficiency by the national, state and municipal governments, asking that they be given that study and care that has proved so broad an economy in the case of live stock and farm crops, and reaffirming its belief in the health conservation principles and methods endorsed by the Second National Conservation Congress. Other resolutions were also adopted, one on the pollution of streams, by sewage and trade wastes, which called on all governments to pass legislation to prevent the pollution of all waters and coast waters, and to formulate regulations regarding the pollution of streams, conforming to the requirements of the law already in force in Pennsylvania; and also one amplifying that of the American Medical Association, advocating that public health be taught in all schools and enumerated ten conditions against which there should be legislative and administrative action. These included blindness of infants, birth accidents, infant mortality, communicable diseases of childhood, work by immature children, occupational diseases and occupational accidents, especially transportation and mining. The congress emphatically showed its approval of the national department of health, by tabling by an almost unanimous vote a motion to strike out an endorsement of such a department. The speeches best received were those on medical subjects and that of Dr. Harvey W. Wiley received more applause than any other address presented. The address by Judge Ben Lindsay of Denver on "The Care of the City and Country Child," also received much attention. He considered chiefly the physical side, the diseases of childhood and infant mortality and the neglect of the health side of the child. The suggestion for a national child's bureau was formulated. It must be understood that this congress was chiefly devoted to soil conservation and soil fertility and most of the delegates were connected with farming, mining, forestry and water interests, and that these problems consequently were chiefly in evidence.

International Pure Water Association.—The Great Lakes Basin International Pure Water Association was organized in Chicago, September 29, and the following officers were elected: President, Dr. Clyde E. Ford, health officer of Cleveland, O.; vice-president, Dr. Chas. J. C. O. Hastings, health officer of Toronto, Ont.; secretary, Prof. Edward Bartow, Urbana, Ill.; editor, Dr. William A. Evans, Chicago; and member of the executive committee, Dr. Francis E. Fronczak, Buffalo, N. Y. The reason for the formation of the association is the growing pollution of the water of the Great Lakes.

Railway Surgeons to Meet.—The American Association of Railway Surgeons will hold its annual meeting at Hotel La Salle, Chicago, October 18-20, under the presidency of Dr. A. R. Mitchell, Lincoln Neb.——The twenty-first annual session of the New York and New England Association of Railway Surgeons will be held at the Hotel Astor, New York City, November 16, under the presidency of Dr. Frederick A. Goodwin, Binghamton, N. Y.——The tenth annual meeting of the Association of Seaboard Air Line Railway Surgeons will be held in the New Willard Hotel, Washington, October 17-18, under the presidency of Dr. Jarvis G. Dean, Dawson, Ga.

Railway Surgeons in Session.—The fourth annual meeting of the Railway Surgeons' Association of the Pennsylvania Railroad Lines East of Pittsburgh, was held at Atlantic City, N. J., September 22-23, under the presidency of Dr. Spencer M. Free, Du Bois, Pa. The following officers were elected: president, Dr. Laban T. Bremerman, Dowington, Pa.; vice-presidents, Drs. Edward B. Heckel, Pittsburgh, Pa., and Dr. E. E. Harrison, Baltimore, Md.; secretary, Dr. Amos W. Colcord, Clairton, Pa. (reelected), and treasurer, Dr. Eugene H. James, Harrisburg, Pa. (reelected). It was decided to hold the next meeting in Atlantic City, just prior to the meeting of the American Medical Association.

Academy Meeting.—The sixteenth annual session of the American Academy of Ophthalmology and Oto-Laryngology opened in the convention hall of the Claypool Hotel, Indianapolis, September 25, with Dr. John J. Kyle, of Indianapolis, as president. The annual address was given by Dr. Albert Gray, of Glasgow, his subject being "The Problem of Otosclerosis and Allied Conditions." In recognition of his contributions to otological science he was elected an honorary member of the Academy and awarded a gold medal. On Monday evening occurred the annual dinner. The following officers were elected: president, Dr. George F. Suker, Chicago; secretary, Dr. Lee M. Francis, Buffalo; treasurer, Dr. Secord H. Large, Cleveland; vice-presidents, Drs. John W. Murphy, Cincinnati, Edward C. Ellett, Memphis, Tenn., and Thomas E. Carmody, Denver, and councilors, Drs. Emil Mayer, New York, James M. Ray, Louisville. Resolutions advocating separate rooms in public schools for children with defective vision and inspection of all public school children with the aim of conserving their sight and hearing were adopted. The next meeting will be at Atlantic City or Chattanooga.

FOREIGN NEWS

Retirement of Kernig.—The chief of the Obuchow hospital for women at St. Petersburg, Dr. W. Kernig, has retired after forty-seven years of service. The city authorities have appointed him for life as consulting physician to the hospitals and on the board of hospital medical directors. Kernig's name is best known by his sign of meningitis.

Cholera in Europe.—According to *Public Health Reports*, September 22, there were sixty-three cases of cholera in Naples the week ending September 2, 220 cases in Leghorn, and 1,377 cases throughout Italy with 613 deaths. The total for Italy June 8 to September 15 has been 10,397 cases and 4,123 deaths. The cable has reported rioting and "rescue" from the doctors of cholera patients from the hospitals in two towns in the extreme south of Italy. The hospital at Massafra was set on fire by the mob and two cholera patients were burned and one of the doctors was seriously wounded. It is significant that none of our Italian medical exchanges mentions even the presence of cholera in Italy this year. They chronicle the appearance of cholera at various points in Turkey and other countries, but when it comes to Italy—"Nice weather we are having." This reticence to date has been so universal and complete that it suggests compulsion. The only reference to the cholera that we have noticed in any of our Italian exchanges is a quotation from a daily paper relating an interview with Professor Sclavo in regard to the campaign against cholera last year of which he had charge. He said "Bacteriologic skill is not needed so much in fighting an epidemic as good practical common sense. In our campaign we were constantly at work. in the schools, factories, prisons and in families, lecturing, talking and distributing circulars giving simple plain directions for hygiene, a hygienic ten commandments. Our force was constantly on the go, talking and interrogating everyone. on the streets, in the market places, in street cars, etc., asking questions and inculcating the principles of hygiene in old and young, adults and children. Local hygiene propaganda committees were organized everywhere which did most valuable service, and prizes of $1 or $2 were given for the best cleaned up houses and families."

PARIS LETTER

(From Our Regular Correspondent)

PARIS, Sept. 15, 1911.

Contraband Trade in Saccharin

Following the recent drought there has been a shortage in the beet-sugar crop in Germany and Austria as well as in France, and it is now likely that saccharin will again make its appearance on the market. Its manufacture and use are not, however, permitted in France, except for pharmaceutic purposes, and then only under strict oversight by the customs officials. Unfortunately, however, it has always been difficult to prevent smuggling across the Belgian frontier from Holland and across the eastern frontier from Switzerland. Still, thanks to the supervision exercised, smuggling is comparatively slight in France, especially compared to that practiced in Russia, where the use of saccharin is likewise forbidden. In view of the existing difficulty—her boundaries being entirely of land—in the struggle against smuggling, Russia has taken the initiative in forming an international conference to take measures against this smuggling which is so disastrous both from the point of view of public health and of money interests. This conference was held at Paris. Germany, Austria, Belgium, Denmark, Greece, Holland, Hungary, Italy, Portugal, Russia, Sweden and Switzerland were represented. The propositions suggested by France were unanimously accepted. It was not a question of keeping watch over smuggling, but simply of the right of control over the firms which manufacture saccharin (Switzerland has six, Germany two and Austria one), of supervising the manufacture and of seeing that the product crosses the frontiers only under properly guaranteed conditions. Representatives from the different powers which took part in the conference will meet in Paris about October 1 to sign the decisions agreed on, and thus it is hoped that smuggling of saccharin will be definitely done away with.

The Prevalence of Heat and Odors at Paris

In spite of the advanced season, the heat continues in Paris. the temperature in the afternoon being as much as 34 C. (93 F.), and at the middle of the day about 10 degrees higher than the normal. In addition to the normal inconveniences of extremely hot weather. there are also those of scarcity of water on the one hand, and on the other the bad odors which permeate the city. On several occasions the water department has been obliged to shut off the supply of water from midnight until 6 o'clock in the morning. As to the odors. they are most noticeable around the manufactories in the suburbs. It is true that for fifteen years the prefect of police has not authorized the opening of a single ill-smelling factory, but unfortunately those already existing continue to operate, and their inconveniences are particularly felt at this season.

Death of Professor Girod

The death of Dr. Paul Girod. professor of natural history at the Ecole de médecine de Clermont. is announced.

BERLIN LETTER

(From Our Regular Correspondent)

BERLIN, Sept. 15, 1911.

Personal

After Professor Sauerbruch, now at Zurich, had declined the call to be director of the surgical clinic at Königsberg, the invitation was extended to Professor Friedrich of Marburg. It is doubtful if he will accept.

September 13. Professor Leopold, director of the royal gynecologic clinic at Dresden, died at his summer home. He had reached the age of 65. Leopold belonged among the most prominent gynecologists. He was a pupil of the well-known Leipsic gynecologist. Credé. In 1874, Leopold joined the Leipsic faculty and in 1883 he succeeded Professor Winckel as director of the Dresden gynecologic clinic after Winckel had accepted the position of director of the university gynecologic clinic at Munich. Leopold has published a large number of scientific works. We may mention his studies of the uterine mucosa. of the scoliotic pelvis, of Cesarean section in artificial premature labor, and of the structure of the placenta. The latest edition of the Saxony official manual for midwives was prepared by him. Since 1894 he has belonged to the editorial staff of the *Archiv für Gynäkologie.* He married a daughter of Credé.

International Congress for Laryngology

In the latter part of August and the early part of September, the third international congress of laryngology held its sessions here. About 400 members assembled from all countries and the scientific proceedings were very active. To be sure no great subjects were debated and. so far as known, no new inventions were presented. It is worth noticing that the congress appointed a special committee to introduce a collective investigation of ozena and report to the next congress which will meet in Copenhagen in 1915. As is the custom, there were a number of banquets which were chiefly instituted by the laryngologic society of this place. It should not go unmentioned that the badge of the congress contained as an important feature the reflector of a laryngeal mirror. This innovation opens a fruitful perspective for future congresses; we may expect at the next gynecologic congress that the badge will represent a pair of forceps or some other characteristic object.

Infant Mortality this Year During the Great Heat

The extraordinarily high temperature of the past summer, as was to be expected. resulted in a great increase in infant mortality. This is shown by a compilation recently published by the director of the bureau of statistics of our neighboring city Schöneberg. In the first two weeks of July there were 1,031 and 1,200 deaths of infants and even the week from July 16 to 22. which in many places produced unbearably hot days. required only 1,368 victims, which is less than the average of August of last year. But in the week from July 23 to 29 the number increased to 2,539 and then rose to 2,866, reaching in the week of August 6 to 12 its highest point, 3,381. The heat abated the following week, but this was unable to diminish the toll of deaths to any considerable extent, for still 3,307 children succumbed; it was not until the week of August 20 to 26 that the number of deaths fell to 2,856.

For all the larger German cities, the mortality for the two weeks from August 6 to 19 was three times as high as from July 2 to 15. In some of the large cities, particularly in the Rhine provinces. the difference was even greater. In Aix la Chapelle, Krefeld. Mülheim and Plauen from August 6 to 19 from five to seven times as many children died as from July 2 to 15. and in Düsseldorf and Hamborn from five to six times as many. In Hamborn and Chemnitz the infant mortality in the week from July 13 to 19 reached a height equivalent to an annual mortality of more than 100 per cent. The same was true of Leipsic in the week of August 6 to 13 and of Erfurt for the week of July 23 to 29. In the five weeks period from July 23 to August 26 the mortality was highest in Leipsic. being 88.5 per cent., Duisburg 81.8 per cent., Hamborn 80.7. Chemnitz 78.0. Erfurt 74.3. Aix la Chapelle 74.0. Cologne 73.2. and in Halle 71.3 per cent. In all these cities the babies were literally decimated in the short space of five weeks. The average mortality for the forty-eight larger cities was 45.2 per cent.. more than double that in July and August of last year. In many large cities the increase was considerably greater. A smaller rate was found only in Kiel and Königsberg. If the mortality in the large cities of Germany had been the same as in the previous year. as many as 9,000 children would have lived who fell victims to the murderous heat.

and fractured and lacerated the fingers of the hand.——Dr. Warner B. Strong, Health Commissioner of Waukesha, has resigned and will remove to St. Martins.——Dr. David W. Ashum, Eau Claire, who is ill at the Sacred Heart Hospital, is reported to be convalescing.

GENERAL NEWS

Leper Deported.—Acieto Paleby, a Philippino leper, who has been held in isolation in Washington for six months, was deported on the transport *Dixon* which sailed from Seattle for Manila, September 15.

It is significant that none of our Italian medical exchanges mentions even the presence of cholera in Italy this year. They chronicle the appearance of cholera at various points in Turkey and other countries, but when it comes to Italy—"Nice weather we are having." This reticence to date has been so universal and complete that it suggests compulsion. The only reference to the cholera that we have noticed in any of our Italian exchanges is a quotation from a daily paper relating an interview with Professor Sclavo in regard to the campaign against cholera last year of which he had charge. He said "Bacteriologic skill is not needed so much in fighting an epidemic as good practical common sense. In our campaign we were constantly at work, in the schools, factories, prisons and in families, lecturing, talking and distributing circulars giving simple plain directions for hygiene, a hygienic ten commandments. Our force was constantly on the go, talking and interrogating everyone, on the streets, in the market places, in street cars, etc., asking questions and inculcating the principles of hygiene in old and young, adults and children. Local hygiene propaganda committees were organized everywhere which did most valuable service, and prizes of $1 or $2 were given for the best cleaned up houses and families."

PARIS LETTER

(*From Our Regular Correspondent*)

PARIS, Sept. 15, 1911.

Contraband Trade in Saccharin

Following the recent drought there has been a shortage in the beet-sugar crop in Germany and Austria as well as in France, and it is now likely that saccharin will again make its appearance on the market. Its manufacture and use are not, however, permitted in France, except for pharmaceutic purposes, and then only under strict oversight by the customs officials. Unfortunately, however, it has always been difficult to prevent smuggling across the Belgian frontier from Holland and across the eastern frontier from Switzerland. Still, thanks to the supervision exercised, smuggling is comparatively slight in France, especially compared to that practiced in Russia, where the use of saccharin is likewise forbidden. In view of the existing difficulty—her boundaries being entirely of land—in the struggle against smuggling, Russia has taken the initiative in forming an international conference to take measures against this smuggling which is so disastrous both from the point of view of public health and of money interests. This conference was held at Paris. Germany, Austria, Belgium, Denmark, Greece, Holland, Hungary, Italy, Portugal, Russia, Sweden and Switzerland were represented. The propositions suggested by France were unanimously accepted. It was not a question of keeping watch over smuggling, but simply of the right of control over the firms which manufacture saccharin (Switzerland has six, Germany two and Austria one), of supervising the manufacture and of seeing that the product crosses the frontiers only under properly guaranteed conditions. Representatives from the different powers which took part in the conference will meet in Paris about October 1 to sign the decisions agreed on, and thus it is hoped that smuggling of saccharin will be definitely done away with.

The Prevalence of Heat and Odors at Paris

In spite of the advanced season, the heat continues in Paris, the temperature in the afternoon being as much as 34 C. (93 F.), and at the middle of the day about 10 degrees higher than the normal. In addition to the normal inconveniences of extremely hot weather, there are also those of scarcity of water on the one hand, and on the other the bad odors which permeate the city. On several occasions the water department has been obliged to shut off the supply of water from midnight until 6 o'clock in the morning. As to the odors, they are most noticeable around the manufactories in the suburbs. It is true that for fifteen years the prefect of police has not authorized the opening of a single ill-smelling factory, but unfortunately those already existing continue to operate, and their inconveniences are particularly felt at this season.

Death of Professor Girod

The death of Dr. Paul Girod, professor of natural history at the Ecole de médecine de Clermont, is announced.

BERLIN LETTER

(*From Our Regular Correspondent*)

BERLIN, Sept. 15, 1911.

Personal

After Professor Sauerbruch, now at Zurich, had declined the call to be director of the surgical clinic at Königsberg, the invitation was extended to Professor Friedrich of Marburg. It is doubtful if he will accept.

September 13. Professor Leopold, director of the royal gynecologic clinic at Dresden, died at his summer home. He had reached the age of 65. Leopold belonged among the most prominent gynecologists. He was a pupil of the well-known Leipsic gynecologist, Credé. In 1874, Leopold joined the Leipsic faculty and in 1883 he succeeded Professor Winckel as director of the Dresden gynecologic clinic after Winckel had accepted the position of director of the university gynecologic clinic at Munich. Leopold has published a large number of scientific works. We may mention his studies of the uterine mucosa, of the scoliotic pelvis, of Cesarean section in artificial premature labor, and of the structure of the placenta. The latest edition of the Saxony official manual for midwives was prepared by him. Since 1894 he has belonged to the editorial staff of the *Archiv für Gynäkologie*. He married a daughter of Credé.

International Congress for Laryngology

In the latter part of August and the early part of September, the third international congress of laryngology held its sessions here. About 400 members assembled from all countries and the scientific proceedings were very active. To be sure no great subjects were debated and, so far as known, no new inventions were presented. It is worth noticing that the congress appointed a special committee to introduce a collective investigation of ozena and report to the next congress which will meet in Copenhagen in 1915. As is the custom, there were a number of banquets which were chiefly instituted by the laryngologic society of this place. It should not go unmentioned that the badge of the congress contained as an important feature the reflector of a laryngeal mirror. This innovation opens a fruitful perspective for future congresses; we may expect at the next gynecologic congress that the badge will represent a pair of forceps or some other characteristic object.

Infant Mortality this Year During the Great Heat

The extraordinarily high temperature of the past summer, as was to be expected, resulted in a great increase in infant mortality. This is shown by a compilation recently published by the director of the bureau of statistics of our neighboring city Schöneberg. In the first two weeks of July there were 1.031 and 1,200 deaths of infants and even the week from July 16 to 22, which in many places produced unbearably hot days, required only 1,368 victims, which is less than the average of August of last year. But in the week from July 23 to 29 the number increased to 2,539 and then rose to 2.866, reaching in the week of August 6 to 12 its highest point, 3,381. The heat abated the following week, but this was unable to diminish the toll of deaths to any considerable extent, for still 3.307 children succumbed; it was not until the week of August 20 to 26 that the number of deaths fell to 2.856.

For all the larger German cities, the mortality for the two weeks from August 6 to 19 was three times as high as from July 2 to 15. In some of the large cities, particularly in the Rhine provinces, the difference was even greater. In Aix la Chapelle, Krefeld, Mülheim and Plauen from August 6 to 19 from five to seven times as many children died as from July 2 to 15, and in Düsseldorf and Hamborn from five to six times as many. In Hamborn and Chemnitz the infant mortality in the week from July 13 to 19 reached a height equivalent to an annual mortality of more than 100 per cent. The same was true of Leipsic in the week of August 6 to 13 and of Erfurt for the week of July 23 to 29. In the five weeks period from July 23 to August 26 the mortality was highest in Leipsic, being 88.5 per cent., Duisburg 81.8 per cent., Hamborn 80.7, Chemnitz 78.0, Erfurt 74.3, Aix la Chapelle 74.0, Cologne 73.2, and in Halle 71.3 per cent. In all these cities the babies were literally decimated in the short space of five weeks. The average mortality for the forty-eight larger cities was 45.2 per cent., more than double that in July and August of last year. In many large cities the increase was considerably greater. A smaller rate was found only in Kiel and Königsberg. If the mortality in the large cities of Germany had been the same as in the previous year, as many as 9.000 children would have lived who fell victims to the murderous heat.

Medical Care for the Members of Soldiers' Families

Since 1909 the management of the army has provided medical care for those belonging to the families of soldiers. Hospital treatment was given when deemed necessary by the army surgeon and the cost of board and nursing was charged to the empire. Furthermore specially educated medical officers are sent from other garrisons for special cases, operations, etc. While in the beginning these treatments were given only for life-saving operations it is now extended to a variety of cases in which hospital care is desirable. Provisions are also made for transporting the sick members of soldiers' families to sanatoria. The entire cost of the increased hospital treatment is estimated at $50,000 (200,000 marks) yearly, for which heretofore only 20,000 marks were appropriated.

VIENNA LETTER

(From Our Regular Correspondent)

Vienna, Sept. 23, 1911.

Care of Tuberculous Patients in Vienna

It was only a few years ago that our authorities and organizations grappled with the problem of controlling tuberculosis; nevertheless, the results obtained so far are very promising. First of all, two public sanatoriums have been erected, but, although equipped in up-to-date manner, they are generally admitted to be sadly insufficient, a large number of such institutions being needed. The Krankenkassen have instituted a special tuberculosis service for their members, and the relative importance of this service may be judged from the fact that of a population of 2,000,000. the three principal Krankenkassen alone count fully 400,000 (20 per cent.) as their members, and altogether about 50 per cent. of the wage-earning population is under the influence of the Kassen and thus may profit by the system, which may be described as follows: The physician is required to report each case of tuberculosis, or what he thinks may be an incipient case, to a central board, which causes the patient to be examined by a specialist. If found to be tuberculous and capable of treatment the patient is submitted to a course of tuberculin injections by a competent tuberculosis specialist, or, as the case may be, is sent to a convalescent home or a private sanatorium. In the meantime, his conditions of living are investigated, note is made of his environment, etc., so that the course of the disease may be controlled. Valuable information is thus gathered as to the ultimate fate of such patients. Thus in the "Gremial" Krankenkasse, which has a membership of 33,000, about 600 cases are on the control list, while the total number of tuberculous members is estimated at 1,500. Another large body is the Krankenkasse of the trade-unions, which has a membership of 300,000, and to which in 1909, about 15,000 notifications of illness and 600,000 days lost on account of tuberculosis were reported. This organization contributes fully one-third of all fatal cases in Vienna among persons over 15 years of age. Some 7,000 patients who were on the sick list for other reasons proved to be tuberculous, and 22,000 members of this organization may be estimated as tuberculous. One feature of the gigantic mechanism required is the appointment of specialists to treat with tuberculin all patients who are still able to work. This is as yet a huge experiment, having been in force only since January, 1911, though some of the organizations have already reported very favorably on the procedure. A centralized control has also been adopted here.

BUDAPEST LETTER

(From an Occasional Correspondent)

Budapest, Sept. 6, 1911.

Pellagra in Hungary

A recent report of the public health service of Transylvania (the southeastern part of Hungary), announces the appearance of pellagra which is spreading rapidly. As generally held here, the disease is due to eating damaged maize, and the prevalence of it is not surprising in view of the fact that maize is the staple food of the peasantry in this part of Hungary. The maize is rendered unwholesome by the modern intensive method of cultivation, the grain being harvested while still unripe, with the result that putrefaction occurs. In parts of Italy, especially in Lombardy and Piedmont, and also in Roumania, pellagra is even more common than in Hungary. The government of Hungary has distributed wheat flour among the indigent inhabitants of southern Hungary. The disease itself is by no means severe, though some patients suffer from mental disturbance which does not yield readily to treatment. Many of the sick with pellagra recover when supplied with wholesome food.

The Relation of Alcoholism to Crime

At a meeting of the Society of Medical Practitioners held on September 2, Dr. Gerö, medical expert attached to the law courts, reported that he has had to examine ninety-four individuals charged with homicide or attempted homicide. In this number there were six malingerers and four persons who were wrongly supposed to be the subject of mental defects. Of the remaining eighty-four criminals seventy were males and only fourteen were females. With regard to their condition of health, the following conditions were noted: one case of pregnancy with mental derangement, one case of morphinomania, one case of hysteria, nine cases of delusions of persecution, seven cases of various states of mental disorder, eight cases of hysteria or epilepsy, thirteen cases of various diseases either supposed or known to have an effect on the brain, ten cases of mental defect, and thirty-four cases of alcoholism.

Dr. Gerö emphasized the fact that the cases of alcoholism thus formed more than one-third of the total number of persons charged with homicide. He added that the influence of alcohol as a contributory cause of homicide would be seen to be even greater if, instead of a mere enumeration of accused individuals personally addicted to alcohol, an examination were made of the antecedents under other headings. This would show that many epileptics and mental defectives were the children of alcoholic parents. Gerö went on to say that acts of extreme violence might be committed not only by habitual inebriates but also by persons in a state of occasional alcohol intoxication, in illustration of which he quoted two cases.

Marriages

Herbert Lentz Freeland, M.R.C., U. S. Army, to Miss Emma E. Pritchard of Los Angeles, Cal., at Manila, P. I., August 14.

George Plummer Howe, M.D., Lawrence, Mass., to Miss Marion Dudley Endicott of Boston, Mass., September 20.

George B. Scholl, M.D., Baltimore, to Miss Ethel Waterbury Jones, at Drexel Hill, Philadelphia, September 20.

Wilfrid Adelard Plourde, M.D., Overly, N. Dak., to Miss Blance Desilets of Grandes Piles, Canada, September 4.

Bert Chamberlain Kern, M.D., Mogollon, N. Mex., to Miss Eva Jackson of Colorado Springs, Colo., September 27.

Edwin Luther Stevens, M.D., Des Moines, Ia., to Miss Mabel Quam Hilbish of Sheridan, Ill., September 21.

Francis R. Blanchard, M.D., Lakeview, Mich., to Miss Lottie Castle of Richland, Mich., September 20.

Walter Bayard Huey, M.D., El Campo, Tex., to Miss Caroline Jerusha Burry of Chicago, September 27.

Charles G. Mixter, M.D., Boston, to Miss Helen Worthington McIntosh of Milwaukee, October 5.

Martin Russ Edwards, M.D., Shanghai, China, to Miss Ethel Hooper of Chicago, September 27.

Snyder R. Miller, M.D., Windsor Hills, Baltimore, to Miss Nell Miller of Pittsburgh, September 7.

Edwin Janas, M.D., Los Angeles, Cal., to Miss Florence Cluff of San Francisco, September 12.

Carl Richard Bassler, M.D., Elkhart, Ind., to Miss Edna Hollinger of Pittsburgh, September 6.

Harry Lorenzo James, M.D., Springfield, Ill., to Miss Mildred Falk of Chicago, January 14.

Arthur H. R. Krueger, M.D., to Miss Grace Wolter, both of Carpentersville, Ill., September 27.

Harold A. Hume, M.D., Owosso, Mich., to Miss Nina Beebe of Ovid, Mich., September 20.

Albert Brewer Landrum, M.D., to Miss Flora Esther Rohe, both of Columbus, O., June 12.

C. Ben Wiley, M.D., to Miss Lucille Johnson, both of Winkelman, Ariz., September 14.

Bert P. Cole, M.D., to Miss Rose M. Persinger, both of Kenney, Ill., September 8.

William Jason Mixter, M.D., to Miss Dorothy Fay, both of Boston, September 21.

Angus MacIver, M.D., Marysville, O., to Miss Gladys Jewell, of Peoria, September 21.

Walter L. Clay, M.D., to Miss Meta Henderson, both of Hannibal, Mo., recently.

Amzi S. Plummer, M.D., to Miss Bessie I. Pitney, both of Peoria, September 6.

Deaths

John Titus Hay, M.D., for many years superintendent of the Nebraska Hospital for the Insane, Lincoln, an alienist of distinction, and a gentle and unassuming man whose life was devoted to helping sufferers from mental disorders; died September 28, from arteriosclerosis, aged 62.

He was born at Schoharie, N. Y., Aug. 3, 1849, and secured his medical degree from the University of the City of New York in 1878. A year later he became first assistant physician at the State Insane Hospital, Lincoln, and served in that position for fourteen years. In 1893 he was appointed superintendent, but with the change of administration he was removed. He was again appointed assistant physician in the State Hospital by Governor Dietrich and again made superintendent by Governor Mickey and held this position through the administration of Governor Sheldon, being succeeded in 1909 by Dr. Woodward. Governor Aldrich, on assuming office in February, 1911, reappointed Dr. Hay superintendent of the institution.

In the interims Dr. Hay practiced medicine in Lincoln, specializing in nervous and mental diseases and acting as alienist for the Lancaster County Board of Examiners and as a member of the County Insanity Commission. He was a member of the American Medical Association and the state and county medical societies.

Henry Herbert Herbst, M.D. University of Pennsylvania, Philadelphia, 1881; a member of the American Medical Association; chairman of the medical section of the Medical Society of the State of Pennsylvania, and first vice-president of the society, and a member of the American Academy of Medicine; at one time coroner's physician; formerly mayor of Allentown, Pa., and for nine years president of the board of control; for several years a member of the board of health and school director in 1894; a pioneer in the medical inspection of public school children; died in the University of Pennsylvania Hospital, Philadelphia, September 20, from disease of the kidneys, aged 53.

James Curtis Hepburn, M.D. University of Pennsylvania, Philadelphia, 1836; for more than forty years a medical missionary in China, the Straits Settlements and Japan; who issued the first Japanese-English dictionary and assisted in the first translation of the Bible into Japanese, and for this and other work was given the insignia of the Imperial Order of the Rising Sun by the Emperor of Japan; died at his home in East Orange, N. J., September 21, from senile debility, aged 96.

Jefferson Dudley Poindexter, M.D. College of Physicians and Surgeons, Baltimore, 1886; a cadet at the United States Military Academy, West Point, N. Y., in 1883 and 1884; who entered the Medical Corps of the Army in 1887, and was made captain in 1892; was retired with the rank of major in 1901 on account of disability in line of duty, and since his retirement has been a resident of Danville, Va.; died at his home in that place, September 10, aged 45.

William Alexander Graham, M.D. University of Pennsylvania, Philadelphia, 1899; a member of the American Medical Association; medical director of Watts Hospital in Durham, N. C., in 1906; attending physician to Watts and Lincoln hospitals and city health officer; died at his home at Durham, September 19, from the effects of a gunshot wound in the head believed to have been self-inflicted with suicidal intent while despondent, aged 35.

Byron Caldwell Hendershott, M.D. Miami Medical College, Cincinnati, 1892; formerly a member of the American Medical Association; chief of staff of the Union Hospital, Canal Dover and New Philadelphia, O.; local surgeon of the Pennsylvania and Baltimore and Ohio systems; president of the local board of U. S. pension examining surgeons; died at his home in New Philadelphia, September 22, from cerebral hemorrhage, aged 43.

Samuel L. Cheaney (license, Illinois Army Board, 1862; Illinois State Board of Health, years of practice, 1880); a practitioner since 1858; assistant surgeon and later surgeon of the Twenty-Ninth Illinois Volunteer Infantry during the Civil War; for many years a leading practitioner of Harrisburg, Saline County, Ill., and state senator in 1878; died at the home of relatives at Henderson, Ky., August 27, aged 76.

William J. Stanford, M.D. University of Nashville (Tenn.), 1858; surgeon in the Confederate service throughout the Civil War; for twenty-two years a practitioner of Ben Wheeler, Tex.; died at the home of his son in Canton, June 11, aged 76.

Hiram Gettman DuBois, M.D. University of Buffalo, N. Y., 1866; a member of the American Medical Association; once president, twice vice-president and a permanent member of the Oneida County Medical Society; in 1881, 1893 and 1896 coroner of Oneida County; for many terms village trustee of Camden; died at his home, September 19, from cerebral hemorrhage, aged 74.

Reed B. Burnham, M.D., Starling Medical College, Columbus, O., 1894; a member of the American Medical Association, and National Association of U. S. Examining Surgeons; from 1895 to 1900 assistant surgeon at the Ohio State Soldiers' and Sailors' Home; died at his home in Piqua, O., recently, and was buried September 17, aged 44.

Edward Winslow Warren, M.D. Harvard Medical School, 1883; afterward district physician at the Boston dispensary; for three years a practitioner of Ansonia, Conn., and thereafter of Boston; especially interested in laryngologic and bacteriologic research; died at his home in Boston, June 28, from pneumonia, aged 55.

James H. Dickerson, M.D. Philadelphia University, 1870 (license, Illinois, years of practice, 1878); Missouri Medical College, St. Louis, 1899; a member of the American Medical Association; local surgeon of the Wabash system at Taylorville; died at his home in that city, September 15, from pneumonia, aged 64.

Edgar Lee Freiberger, M.D. Denver and Gross College of Medicine, Denver, 1906; a member of the Colorado State Medical Society; a specialist in diseases of the eye, ear, nose and throat, who recently erected the Alamosa Hospital; died in that institution, September 16, from sarcoma, aged 38.

Martin Lucius Fielder, M.D. Graffenburg Institute, Dadeville, Ala., 1859; an honorary member of the Medical Association of the State of Alabama; for several years superintendent of the Soldiers' Home, Mountain Creek; died suddenly at his home in Wetumpka, September 18, aged 76.

John J. Pickett, M.D. Curtiss Physio-Medical Institute, Marion, Ind., 1884; a member of the Nebraska State Medical Association; district surgeon of the Union Pacific system; died at his home in Broken Bow, September 13, from cerebral hemorrhage, aged 61.

John A. Vieregge, M.D. St. Paul (Minn.) Medical College; (license, Minnesota, examination, 1887) a member of the Ramsey County Medical Society; died at his home in St. Paul, September 17, from diabetes, aged 50.

J. C. M. Cunningham, M.D. Cooper Medical College, San Francisco, 1900; of San Francisco; surgeon on the steamer *San Juan;* died on that boat, July 28, from heat exhaustion, off the coast of Central America, aged 34.

William Henry Cope, M.D. Cooper Medical College, San Francisco, 1887; district surgeon for the Southern Pacific system; died at his home in Pleasanton, Cal., May 28, from chronic interstitial nephritis, aged 59.

Lawrence Sterling Alexander, M.D. University of Maryland, Baltimore, 1868; since 1880 a practitioner of St. Augustine, Fla.; died at his home in that city, Nov. 6, 1910, from heart disease, aged 68.

Samuel R. Berg, M.D. Iowa Medical College, Eclectic, Des Moines, 1889; formerly city physician of Independence, Mo., and later a resident of Holden, Mo.; died in Warrensburg, Mo., September 19.

William Lee Berry, M.D. Cooper Medical College, San Francisco, 1889; of Tonapah, Nev.; died in the Miners' Hospital in that city, September 21, from hemorrhage of the stomach, aged 46.

Albert E. Gundry, M.D. Kansas Medical College, Topeka, 1894; of Junction City, Kansas; died in Christ's Hospital, Topeka, September 14, from carcinoma of the stomach, aged 45.

Daniel Franklin Coolidge, M.D. Bellevue Hospital Medical College, 1867; a veteran of the Civil War; died at his home in Ludlow, Vt., September 17, from disease of the brain, aged 71.

William Lorenzo Goodale, M.D. University of Vermont, Burlington, 1888; of Montpelier; died at the Heaton Hospital in that city, September 17, from nephritis, aged 45.

Harriet A. Anderson, M.D. Northwestern University Woman's Medical School, Chicago, 1882; died at her home at Mount Horeb, Wis., September 17, aged 72.

Edwin J. Atkinson (license, Missouri, 1883); a practitioner since 1856; died at his home in Nevada, September 17, from cerebral hemorrhage, aged 81.

George Washington Gaddy (license, Arkansas, 1903), died at his home in Fourche, Dec. 5, 1910, from pneumonia, aged 70.

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession.

THE INTERSTATE REMEDY COMPANY*

A Mail-Order Medical Fake and Its "Free Recipe" Bait

Readers of the less particular newspapers and magazines are doubtless familiar with an advertisement which is headed in bold type: "$3.50 Recipe Cures Weak Men—Free" (Fig. 1). This "free prescription" will be sent, so the advertisement says, by a "Dr." or, as it has sometimes appeared, "Mr." A. E. Robinson, Luck Building, Detroit, Mich. Investigation seems to show that A. E. Robinson is the style adopted by one Andrew Robinson, who some years ago was connected with a fraudulent mail-order "men's specialist" concern in Indiana known as the business in 1904 by the government "for operating through the mails a scheme or device for obtaining money or other property by means of false or fraudulent pretenses, representations or promises." Not only did the Dr. Knapp Medical Company operate a fraud, but it published such filthy newspaper advertisements that some of them were declared to violate the obscenity law.

THE
BAPTIST RECORD.

"Dr. A. E. Robinson," then, is the Interstate Remedy Company and the Interstate Remedy Company is Messrs. Hayes, Bourke and Coon. These three men are, we understand, also the officers and stockholders of another "patent medicine" fake, the Marmola Company. Marmola is an "obesity cure" which has been advertised both by the "fake prescription" method and also direct. According to various analyses, Marmola depends for its action on the presence of thyroid extract, a powerful and, in the hands of the public, a dangerous drug.

The "$3.50 recipe," which Robinson advertises that he will send free, is said to be for "nervous debility, lack of vigor, weakened manhood, failing memory and lame back, brought on by excesses, unnatural drains or the follies of youth . . ." The close resemblance of this advertisement to the dirty sheets put out by the "men's specialist" quacks is apparent. Those who answer the advertisement and ask for the free "recipe" are sent a form-letter which is filled in, here and there, to give it the verisimilitude of a personal communication; they are also sent a booklet entitled "Rational Treatment of Kidney and Bladder Diseases."

cial advantage should have modified the humbug so as to apply it to another branch of their medical frauds.

THE C. O. D. HUMBUG

To go back to the form-letter: No matter what excuse the prospective victim may have given for writing, he is told that his letter "indicates that you need the actual medicines at once also the best medical advice while you are using them." To meet this trumped-up indication, the letter goes on to state:

> "For this reason and in order that there may be no loss of time, also that it may be just as handy for you to get the remedies of this big, old-established company as of your druggist, I have shipped you to-day one full and complete treatment as per the prescription enclosed by Pacific Express, C. O. D. $3.50, which by the time this letter reaches you should be in your express office. I have prepaid the express charges, also the charges for the return of the money to us, so that all you are to pay is $3.50 only for the package."

In some cases, the Interstate Remedy Company sends its package of pills by mail instead of by express. If, in such instances, the recipient of the pills does not send the $3.50, he receives a long series of follow-up letters urging him to remit. Each letter is more insistent than its predecessor until at last one arrives that purports to come from the firm's attorneys and threatens legal reprisal. If the money is still not forthcoming, another "lawyer letter" comes offering to take one-half the amount of the bill!

If, on the other hand, the patient is foolish enough to send $3.50, about a week later he receives another letter—printed so as to indicate a personal typewritten communication—telling him that a month's treatment is on the way and will be delivered by the express company on the payment of $6.00. Of course, "$6.00 is a special price for a month's treatment, being one dollar less than two fifteen-day treatments would cost if sent separately."

BLACKGUARDING THE DRUGGIST

Like most mail-order quacks, the Interstate Remedy Company does not like the druggist any more than it loves the physician. While the Detroit concern states in its booklet that Urikol and Kydnus may be obtained from any druggist on special order, yet it would prefer "that you obtain them from us direct, for several reasons." One of the reasons is that "the medicine should be in tablet form" and, of course, the druggist does not know how to make tablets! Another reason is that "there are a number of ingredients in each of Formulas 1 and 2 and unless they are thoroughly mixed together the synergizing effect is lost." This "synergizing" humbug will sound familiar to physicians who remember the great stress that the purveyors of so-called ethical proprietaries used to lay on this same point a year or two ago in exploiting their wares. "Synergizing" has long been such a favorite piece of clap-trap among the nostrum fraternity that it is entirely fitting that the Interstate Remedy Company should bring it into use.

But the vital reason that you should order Urikol and Kydnus from Messrs. Hayes, Bourke and Coon, *alias* A. E. Robinson, is that "a great many unscrupulous druggists try to deceive their customers into taking something they do not want, and which may be a positive damage to you rather than a benefit." So the patient is warned that if he orders his Interstate Remedy "dope" through his local druggist he should insist on the druggist giving him the empty packages in which Kydnus and Urikol came!

WHAT ARE URIKOL AND KYDNUS?

To determine the composition of the prescription fakes in Formulas 1 and 2, that is, Urikol and Kydnus, it was decided to obtain specimens of these products direct from the Interstate Remedy Company. Accordingly, a Chicago druggist was asked to write direct to the Interstate Remedy Company for an original package of Urikol and an original package of Kydnus. This was done, but the Detroit concern, instead of sending what was ordered, tried to do what it has charged druggists with doing, substitute, and sent one of its packages of pills similar to the regular $3.50 C. O. D. "treatment." This the druggist returned and insisted that he wanted half-ounce packages of Urikol and Kydnus, respectively. These finally came and were turned over to the American Medical Association laboratory for investigation. The Association's chemists reported as follows:

LABORATORY REPORT

Urikol.—The powder in the box labeled "Urikol" is greenish yellow in color and possesses an odor in which, among others, that of buchu is most prominent. Quantitative analysis yielded the following results:

Water-soluble matter	37.93	per cent.
Alcohol-soluble matter	0.55	per cent.
Chloroform-soluble matter	3.67	per cent.
Insoluble matter	52.96	per cent.
Moisture	5.20	per cent.
Undetermined	0.69	per cent.
	100.00	

The portion soluble in water contains what appears to be sugar and some drug extracts, the most prominent appearing to be buchu. The alcohol-soluble part has in general the same properties as the water-soluble portion. The substance soluble in chloroform was identified as hexamethylenamin. The portion insoluble in the above solvents consists approximately of equal parts of starch and calcium carbonate. The remainder of the powder is chiefly moisture. The presence of alkaloids, arsenic or metals could not be demonstrated.

From these results it appears that the powder called Urikol is essentially a small quantity of hexamethylenamin and some drug extracts in a mixture of starch, sugar and calcium carbonate.

Kydnus.—The powder in the box labeled "Kydnus" is light brown in color, possessing a taste and a slight odor of hydrogen sulphid. Quantitative analysis yielded the following:

Water-soluble matter	38.75	per cent.
Dilute acid-soluble matter	27.20	per cent.
Concentrated acid-soluble matter	2.94	per cent.
Insoluble matter	28.08	per cent.
Moisture	2.80	per cent.
Undetermined	0.23	per cent.
	100.00	

The portion soluble in water consists of about 32 per cent. sugar and the rest potassium and calcium sulphates. The acid-soluble part consists of about 27 per cent. calcium carbonate and about 0.2 per cent. calcium sulphid. The portion soluble in concentrated acid consists of iron equivalent to about 3 per cent. ferric oxid. The residue insoluble in the above solvents is practically entirely starch. The remainder of the powder is chiefly moisture.

From these results it is concluded that Kydnus is essentially a mixture of calcium carbonate, starch and sugar containing a small quantity of calcium sulphid and iron.

As usual, of course, it is found that the nostrums used by these quacks are drugs that are in common use by regular physicians. It is the same old story: Well-known drugs enveloped in a cloud of secrecy and mystery, endowed with properties they do not possess and sold at a price enormously in excess of their worth.

"WEAK WOMEN" ALSO

Nor do these quacks confine themselves conclusively to the "recipe for men" fraud. They have, as a sideline, the "Interstate Woman Medicine," by which they are able to humbug suffering women. In their booklet "How Women Cure Themselves at Home" they repeat almost verbatim some of the matter that appears in the other booklet issued to "weak men." To quote:

URIKOL AND KYDNUS	WOMAN MEDICINE
"When a man is young he makes body poisons by the philter full, but the vigor of his tissues casts them forth."	"When a woman is young she makes body poisons by the philter full, but the vigor of her tissues casts them forth."
"The body suffers in brain and muscle and nerve; to greater extent than the liver; most disastrously of all in the kidney."	"The body suffers in brain and muscle and nerve; to greater extent in the liver; most disastrously of all in the kidney, bladder and organs of generation."
"In short, with advancing age a man must seek kidney help. It must be fortified. Its tasks overmaster its strength. Its outcry is feebleness."	"In short, with advancing age a woman must seek help for the vital organs. These are her weak spots. They must be fortified. Their tasks overmaster their strength. Their outcry is feebleness."

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE MEDICAL FRAUD ON THE PUBLIC AND ON THE PROFESSION.

THE INTERSTATE REMEDY COMPANY*

A Mail-Order Medical Fake and Its "Free Recipe" Bait

Readers of the less particular newspapers and magazines are doubtless familiar with an advertisement which is headed in bold type: "$3.50 Recipe Cures Weak Men—Free" (Fig. 1). This "free prescription" will be sent, so the advertisement says, by a "Dr." or, as it has sometimes appeared, "Mr." A. E. Robinson, Luck Building, Detroit, Mich. Investigation seems to show that A. E. Robinson is the style adopted by one Andrew Robinson, who some years ago was connected with a fraudulent mail-order "men's specialist" concern in Indiana known as the "State Medical Institute." Afterward he secured a license to practice in Illinois and in 1904 he registered, by reciprocity, in Michigan. Here he has been employed to act as the stool-pigeon for a mail-order medical concern—the Interstate Remedy Company. This company, advertising under Robinson's name, is incorporated and has the following officers and directors:

EDWARD D. HAYES, President.
WILLIAM H. BOURKE, Vice-President.
HENRY F. COON, Secretary and Treasurer.

ITS UNSAVORY PAST

The Interstate Remedy Company is a successor to the Dr. Knapp Medical Company and the Dr. Raynor Medical Company. The Knapp and Raynor medical companies of Detroit were two names for the same concern, which was put out of business in 1904 by the government "for operating through the mails a scheme or device for obtaining money or other property by means of false or fraudulent pretenses, representations or promises." Not only did the Dr. Knapp Medical Company operate a fraud, but it published such filthy newspaper advertisements that some of them were declared to violate the obscenity law.

"Dr. A. E. Robinson," then, is the Interstate Remedy Company and the Interstate Remedy Company is Messrs. Hayes, Bourke and Coon. These three men are, we understand, also the officers and stockholders of another "patent medicine" fake, the Marmola Company. Marmola is an "obesity cure" which has been advertised both by the "fake prescription" method and also direct. According to various analyses, Marmola depends for its action on the presence of thyroid extract, a powerful and, in the hands of the public, a dangerous drug.

The "$3.50 recipe," which Robinson advertises that he will send free, is said to be for "nervous debility, lack of vigor, weakened manhood, failing memory and lame back, brought on by excesses, unnatural drains or the follies of youth . . ." The close resemblance of this advertisement to the dirty sheets put out by the "men's specialist" quacks is apparent. Those who answer the advertisement and ask for the free "recipe" are sent a form-letter which is filled in, here and there, to give it the verisimilitude of a personal communication; they are also sent a booklet entitled "Rational Treatment of Kidney and Bladder Diseases."

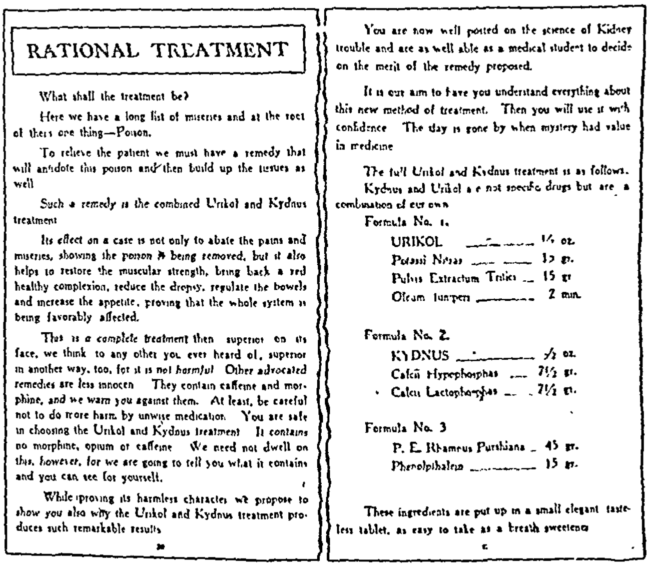
$3.50 Recipe Cures Weak Men - - - FREE

Send Name and Address Today —You Can Have it Free and Be Strong and Vigorous.

This prescription comes from a physician who has made a special study of men, and I am convinced it is the surest-acting combination for the cure of deficient manhood and vigor-failure ever put together.
I think I owe it to my fellow man to send

Fig. 1.—Photographic reproductions (reduced) of the stock advertisement sent out by the Interstate Remedy Company under the name of A. E. Robinson. One of these "lost manhood" advertisements appeared in the *Police Gazette*, the other in the *Baptist Record*. One would expect to find this type of advertising in a sheet like the *Police Gazette*, but in a religious weekly it seems disgustingly incongruous.



RATIONAL TREATMENT

What shall the treatment be?

Here we have a long list of miseries and at the root of them one thing—Poison.

To relieve the patient we must have a remedy that will antidote this poison and then build up the tissues as well

Such a remedy is the combined Urikol and Kydnus treatment

Its effect on a case is not only to abate the pains and miseries, showing the poison is being removed, but it also helps to restore the muscular strength, bring back a red healthy complexion, reduce the dropsy, regulate the bowels and increase the appetite, proving that the whole system is being favorably affected.

This is *a complete treatment* then superior on its face, we think to any other you ever heard of, superior in another way, too, for it is not *harmful* Other advocated remedies are less innocent They contain caffeine and morphine, and we warn you against them. At least, be careful not to do more harm by unwise medication You are safe in choosing the Urikol and Kydnus treatment *It contains* no morphine, opium or caffeine We need not dwell on this, *however, for we are going to tell you what it contains* and you can see for yourself.

While proving its harmless character we propose to *show you* also why the Urikol and Kydnus treatment produces such remarkable results

You are now well posted on the science of Kidney trouble and are as well able as a medical student to decide on the merit of the remedy proposed.

It is our aim to have you understand everything about this new method of treatment. Then you will use it with confidence The day is gone by when mystery had value in medicine

The full Urikol and Kydnus treatment is as follows.
Kydnus and Urikol are not specific drugs but are a combination of our own

Formula No. 1.
URIKOL ———— 1½ oz.
Potassi Nitras ———— 15 gr.
Pulvis Extractum Tritici ——— 15 gr.
Oleum Juniperi ———— 2 min.

Formula No. 2.
KYDNUS ———— ½ oz.
Calcii Hypophosphas ——— 7½ gr.
Calcii Lactophosphas ——— 7½ gr.

Formula No. 3
P. E. Rhamnus Purshiana — 45 gr.
Phenolphthalein ———— 15 gr.

These ingredients are put up in a small elegant tasteless tablet, as easy to take as a breath sweetener

Fig. 2.—Photographic reproduction (reduced) of two pages of the book sent in answer to the request for the free "$3.50 recipe." The "free recipe" is shown on the right-hand page and consists of three formulas, two of which contain "patent medicines"—Urikol and Kydnus—which can be obtained only from the Interstate Remedy Company. In other words, the offer of a "free recipe" is a mere catch-penny cheat.

THE FREE PRESCRIPTION

The form-letter states that the "free prescription" asked for will be found on page 37 of this booklet. On the page mentioned there are to be found (Fig. 2) not one prescription but three, designated respectively as Formulas Nos. 1, 2 and 3.

A study of these prescriptions reveals at once to the physician, although it is not evident to the public, that Formulas 1 and 2 each contain a "joker" in the form of a "patent medicine." That is to say, "Urikol" and "Kydnus" are both secret preparations obtainable only from the Interstate Remedy Company and are not kept in stock by the druggist. This scheme of operating what has been called the "prescription fake" dodge is a comparatively recent innovation on the part of the Interstate Remedy Company. Their older method consisted in sending three bona-fide prescriptions, one of which called for a drug (muirapuama) which while not proprietary was unofficial. It is perfectly natural, however, that the men who have worked the Marmola "prescription fake" to such great finan-

cial advantage should have modified the humbug so as to apply it to another branch of their medical frauds.

---

* This article, like similar ones of interest to the laity, will be reprinted in pamphlet form with additional illustrations and somewhat elaborated; price 4 cents.

THE C. O. D. HUMBUG

To go back to the form-letter: No matter what excuse the prospective victim may have given for writing, he is told that his letter "indicates that you need the actual medicines at once, also the best medical advice while you are using them." To meet this trumped-up indication, the letter goes on to state:

> "For this reason and in order that there may be no loss of time, also that it may be just as handy for you to get the remedies of this big, old-established company as of your druggist, I have shipped you to-day one full and complete treatment as per the prescription enclosed by Pacific Express, C. O. D. $3.50, which by the time this letter reaches you should be in your express office. I have prepaid the express charges, also the charges for the return of the money to us, so that all you are to pay is $3.50 only for the package."

In some cases, the Interstate Remedy Company sends its package of pills by mail instead of by express. If, in such instances, the recipient of the pills does not send the $3.50, he receives a long series of follow-up letters urging him to remit. Each letter is more insistent than its predecessor until at last one arrives that purports to come from the firm's attorneys and threatens legal reprisal. If the money is still not forthcoming, another "lawyer letter" comes offering to take one-half the amount of the bill!

If, on the other hand, the patient is foolish enough to send $3.50, about a week later he receives another letter—printed so as to indicate a personal typewritten communication—telling him that a month's treatment is on the way and will be delivered by the express company on the payment of $6.00. Of course, "$6.00 is a special price for a month's treatment, being one dollar less than two fifteen-day treatments would cost if sent separately."

BLACKGUARDING THE DRUGGIST

Like most mail-order quacks, the Interstate Remedy Company does not like the druggist any more than it loves the physician. While the Detroit concern states in its booklet that Urikol and Kydnus may be obtained from any druggist on special order, yet it would prefer "that you obtain them from us direct, for several reasons." One of the reasons is that "the medicine should be in tablet form" and, of course, the druggist does not know how to make tablets! Another reason is that "there are a number of ingredients in each of Formulas 1 and 2 and unless they are thoroughly mixed together the synergizing effect is lost." This "synergizing" humbug will sound familiar to physicians who remember the great stress that the purveyors of so-called ethical proprietaries used to lay on this same point a year or two ago in exploiting their wares. "Synergizing" has long been such a favorite piece of clap-trap among the nostrum fraternity that it is entirely fitting that the Interstate Remedy Company should bring it into use.

But the vital reason that you should order Urikol and Kydnus from Messrs. Hayes, Bourke and Coon, *alias* A. E. Robinson, is that "a great many unscrupulous druggists try to deceive their customers into taking something they do not want, and which may be a positive damage to you rather than a benefit." So the patient is warned that if he orders his Interstate Remedy "dope" through his local druggist he should insist on the druggist giving him the empty packages in which Kydnus and Urikol came!

WHAT ARE URIKOL AND KYDNUS?

To determine the composition of the prescription fakes in Formulas 1 and 2, that is, Urikol and Kydnus, it was decided to obtain specimens of these products direct from the Interstate Remedy Company. Accordingly, a Chicago druggist was asked to write direct to the Interstate Remedy Company for an original package of Urikol and an original package of Kydnus. This was done, but the Detroit concern, instead of sending what was ordered, tried to do what it has charged druggists with doing, substitute, and sent one of its packages of pills similar to the regular $3.50 C. O. D. "treatment." This the druggist returned and insisted that he wanted half-ounce packages of Urikol and Kydnus, respectively. These finally came and were turned over to the American Medical Association laboratory for investigation. The Association's chemists reported as follows:

LABORATORY REPORT

Urikol.—The powder in the box labeled "Urikol" is greenish yellow in color and possesses an odor in which, among others, that of buchu is most prominent. Quantitative analysis yielded the following results:

Water-soluble matter	37.93	per cent.
Alcohol-soluble matter	0.55	per cent.
Chloroform-soluble matter	3.67	per cent.
Insoluble matter	52.96	per cent.
Moisture	5.20	per cent.
Undetermined	0.69	per cent.
	100.00	

The portion soluble in water contains what appears to be sugar and some drug extracts, the most prominent appearing to be buchu. The alcohol-soluble part has in general the same properties as the water-soluble portion. The substance soluble in chloroform was identified as hexamethylenamin. The portion insoluble in the above solvents consists approximately of equal parts of starch and calcium carbonate. The remainder of the powder is chiefly moisture. The presence of alkaloids, arsenic or metals could not be demonstrated.

From these results it appears that the powder called Urikol is essentially a small quantity of hexamethylenamin and some drug extracts in a mixture of starch, sugar and calcium carbonate.

Kydnus.—The powder in the box labeled "Kydnus" is light brown in color, possessing a taste and a slight odor of hydrogen sulphid. Quantitative analysis yielded the following:

Water-soluble matter	38.75	per cent.
Dilute acid-soluble matter	27.20	per cent.
Concentrated acid-soluble matter	2.94	per cent.
Insoluble matter	28.08	per cent.
Moisture	2.80	per cent.
Undetermined	0.23	per cent.
	100.00	

The portion soluble in water consists of about 32 per cent. sugar and the rest potassium and calcium sulphates. The acid-soluble part consists of about 27 per cent. calcium carbonate and about 0.2 per cent. calcium sulphid. The portion soluble in concentrated acid consists of iron equivalent to about 3 per cent. ferric oxid. The residue insoluble in the above solvents is practically entirely starch. The remainder of the powder is chiefly moisture.

From these results it is concluded that Kydnus is essentially a mixture of calcium carbonate, starch and sugar containing a small quantity of calcium sulphid and iron.

As usual, of course, it is found that the nostrums used by these quacks are drugs that are in common use by regular physicians. It is the same old story: Well-known drugs enveloped in a cloud of secrecy and mystery, endowed with properties they do not possess and sold at a price enormously in excess of their worth.

"WEAK WOMEN" ALSO

Nor do these quacks confine themselves conclusively to the "recipe for men" fraud. They have, as a sideline, the "Interstate Woman Medicine," by which they are able to humbug suffering women. In their booklet "How Women Cure Themselves at Home" they repeat almost verbatim some of the matter that appears in the other booklet issued to "weak men." To quote:

URIKOL AND KYDNUS	WOMAN MEDICINE
"When a man is young he makes body poisons by the philter full, but the vigor of his tissues casts them forth."	"When a woman is young she makes body poisons by the philter full, but the vigor of her tissues casts them forth."
"The body suffers in brain and muscle and nerve; to greater extent than the liver; most disastrously of all in the kidney."	"The body suffers in brain and muscle and nerve; to greater extent in the liver; most disastrously of all in the kidney, bladder and organs of generation."
"In short, with advancing age a man must seek kidney help. It must be fortified. Its tasks overmaster its strength. Its outcry is feebleness."	"In short, with advancing age a woman must seek help for the vital organs. These are her weak spots. They must be fortified. Their tasks overmaster their strength. Their outcry is feebleness."

Insoluble matter	28.08	per cent.
Moisture	2.80	per cent.
Undetermined	0.23	per cent.
	100.00	

The portion soluble in water consists of about 32 per cent. sugar and the rest potassium and calcium sulphates. The acid-soluble part consists of about 27 per cent. calcium carbonate and about 0.2 per cent. calcium sulphid. The portion soluble in concentrated acid consists of iron equivalent to about 3 per cent. ferric oxid. The residue insoluble in the above solvents is practically entirely starch. The remainder of the powder is chiefly moisture.

From these results it is concluded that Kydnus is essentially a mixture of calcium carbonate, starch and sugar containing a small quantity of calcium sulphid and iron.

As usual, of course, it is found that the nostrums used by these quacks are drugs that are in common use by *regular* physicians. It is the same old story: Well-known drugs enveloped in a cloud of secrecy and mystery, endowed with properties they do not possess and sold at a price enormously in excess of their worth.

"WEAK WOMEN" ALSO

Nor do these quacks confine themselves conclusively to the "recipe for men" fraud. They have, as a sideline, the "Interstate Woman Medicine," by which they are able to humbug suffering women. In their booklet "How Women Cure Themselves at Home" they repeat almost verbatim some of the matter that appears in the other booklet issued to "weak men." To quote:

URIKOL AND KYDNUS	WOMAN MEDICINE
"When a man is young he makes body poisons by the philter full, but the vigor of his tissues casts them forth."	"When a woman is young she makes body poisons by *the* philter full, but the vigor of her tissues casts them forth."
"The body suffers in brain and muscle and nerve; *to greater* extent than the liver; most disastrously of all in the kidney."	"The body suffers in brain and muscle and nerve; to greater extent in the liver; *most* disastrously of all in the kidney, bladder and organs of generation."
"In short, with advancing age a man must seek kidney help. It must be fortified. Its tasks overmaster its strength. Its outcry is feebleness."	"In short, with advancing age a woman must seek help *for* the vital organs. These are her weak spots. They must be fortified. Their tasks overmaster their strength. Their outcry is feebleness."

"What even pretty well people should have, we think, is kidney help. The waning power of the body to get rid of its own poisons makes intelligent assistance imperative."	"What even pretty well women should have, we think, is help for weakness. The waning power of the body to get rid of its own poisons makes intelligent assistance imperative."
"It is a duty you owe yourself to take heed of your kidney's health. You have no excuse for neglect. There is little chance for escape in our opinion."	"It is a duty you owe yourself to take heed of your health. You have no excuse for neglect. There is little chance for escape in our opinion."
"Therefore, use the Urikol and Kydnus treatment—it has every recommendation: simple, safe and quick acting, and consequently inexpensive."	"Therefore, use the 'Woman Medicine' treatment — it has every recommendation: simple, safe, quick acting and consequently inexpensive."

All of which means that the Interstate Remedy Company exists not for its pretended purpose of furnishing professional advice and treatment to the ill, but to capitalize sickness and wring dividends from distress.

MAIL-ORDER FAKES

Founded on falsehood, maintained by deceit, dependent on ignorance—mail-order medical fakers are concerned only with the commercializing of suffering. In place of the knowledge of the family physician, they offer only an ignorance that is as dense as it is dangerous; for the kindly personal interest of the home doctor, they substitute a set of "form letters"; instead of the confidential and private consideration of the patient's infirmities, the mail-order quacks give them all the publicity of a large corps of mailing clerks and finally sell the patients' letters to others in the same business; in place of an individualized treatment, they prescribe stock pills and tablets of the cheapest and least reliable kind—instead, in fact, of treating the patient as a suffering, human entity, the victim of sickness is a mere customer in whom the quack is interested only to the extent of the length of his purse or the ease with which he may be swindled.

Correspondence

The Tabulation of Cases of Tuberculosis After Treatment in Sanatoriums or Dispensaries—Follow-Up Work

To the Editor:—In THE JOURNAL, Sept. 2, 1911, occurred a thoughtful article by Dr. Lawrason Brown, of Saranac Lake, concerning "Sanatorium and Dispensary Treatment of Tuberculosis."

In the course of this article the following statement appears:

> A number of dispensaries in America have published reports of the immediate results of treatment, but such figures carry far less weight than the percentage of living, dead and untraced among a number of carefully classified patients. There is no doubt great difficulty in following these patients either to their death or to recovery at the end of five years, but with the excellent facilities at the disposal of many modern dispensaries, such for instance as the visiting nurses, the various relief associations and the hearty cooperation of the boards of health, such work should present no insurmountable difficulties . . . It will be of great value to compare results obtained in the dispensaries before and after the introduction of this method. Many patients from the dispensaries are sent to the sanatoriums. On return they should report to the dispensary. These patients should be studied separately and the problem of the best treatment of tuberculosis might then be solved.

It was with precisely this view that, during the summer of 1909, I appointed two physicians to visit the 115 tuberculosis dispensaries of the State Department of Health of Pennsylvania for the purpose of gathering and tabulating statistics concerning the individual tuberculous patients. It will be borne in mind that the department was not established until 1905 and the appropriation enabling the department to undertake a campaign for the control of tuberculosis was not made until 1907. The dispensary system was inaugurated at the close of that year, but it was not until the middle of the year 1908 that it was perfected.

It will be observed that the only means of admission into state sanatoriums is through a dispensary, the certificate of the dispensary physician being essential.

The examination of the patient on making application at the dispensary is thorough, including family history, environment, previous condition of health, present illness and physical examination, and a nurse's report which goes fully into the sociologic conditions of the family. The certificate of the dispensary physician for admission to a sanatorium contains an expression of opinion as to the stage of the disease, whether incipient, advanced or far advanced. On admission to the sanatorium a careful examination is again made which is repeated at frequent intervals. On the discharge of the patient, the dispensary from which he was accredited to the sanatorium is at once notified and takes up further supervision of the treatment. It becomes the duty of the dispensary nurse, however, if the patient does not again resume attendance on the dispensary, to inspect the patient at his home in March and September of each year and report his condition to the medical director of the sanatorium from which he was discharged. This report indicates the condition of the patient's health in detail, comparative weight and capacity for work, with character of occupation. Thus the basis is laid for following up every case discharged from one of our state sanatoriums for an indefinite number of years. The first of these reports reached the sanatorium at Mont Alto in April, 1911, and the statistics are now being compiled. A similar scheme for the dispensaries has not yet been formulated but is in contemplation.

The reader will note that with the state's sanatoriums and the dispensaries all under the centralized governmental control of the department of health, a scheme of organization is at once available for following up each individual patient until we know how many patients with incipient tuberculosis remain well, how many patients in whom the disease is arrested remain quiescent or go on to cure and how many cured

(Leave above spaces blank for use at Sanatorium.)

Physicians in charge of Dispensary will please instruct Dispensary Nurse to inspect ex-sanatorium patients in March and September of each year
Reports should be forwarded not later than April 15 and October 15
Send reports to Medical Director of Sanatorium of which the patient was an inmate.
A copy of each report should be kept on file in the Dispensary.
Please review each report carefully before mailing, and see that all questions are clearly answered.

patients remain cured after a period of years, and after all until we have compiled such statistics for a period of years we shall not be able to say definitely how much good we are accomplishing with hospital and dispensary treatment.

Accompanying is the blank on which the nurse's report is to be returned.

SAMUEL G. DIXON, M.D., State Health Commissioner,
Harrisburg, Pa.

Virchow and Pasteur

To the Editor:—All those who relish rich and lofty natures, great characters who have marked their impress on a whole generation, and left of their passage a trace that time shall not obliterate, will have read with interest and emotion your editorial in THE JOURNAL, Sept. 9, 1911, page 904. The very day your article was published was the anniversary of that on which Virchow was laid to rest nine years ago; and it was indeed a fitting tribute to him to commemorate on such a day the personality of this great man, and to take as the motto of his eulogy what was the characteristic of his personality: his generosity.

A great scientist, a great educator and above all a great citizen and patriot—Virchow was all that, and to a degree that is uncommon to see combined in a single man. An absolute faith in the progress and the destinies of humanity, to which he had devoted all the gifts of his rich nature, and an ardent and generous sympathy for anything that was noble and great were among the most eminent characteristics of Virchow. And so, when he was called on to take the defense of Pasteur, and to vindicate his memory before the German scientific world, he had no great effort to make: he had only to obey the commands of his lofty nature. As for Pasteur himself, there is a peculiarity concerning his attitude toward Germany which has not been put in the proper light, and which, distorted as it has been by the passions of the time, is apt, if left unchallenged, to misrepresent him before posterity.

Your editorial seems to ascribe Pasteur's unwillingness to accept the distinctions offered him by the German government to a natural soreness over the reverses of his country in the Franco-German war. This is not, however, the true reason of his attitude.

Men of the present generation could not adequately realize the stress of calamities and horrors that were visited on France during that unfortunate war. To recall them to-day would be to revive unnecessarily the bitterness and the animosities of a conflict on which, in the interest of peace and the comity between nations, it is preferable to let impartial history pass judgment. But while we admit that war is war; and that its excesses and violences must be condoned in a spirit of philosophic equanimity, if not of absolute submission, it is nevertheless true that the rigors and the bitterness evinced during the Franco-German conflict must have strained the fibers of patriotism to a point that left in the heart of a man like Pasteur an unconquerable soreness, to put it very mildly. As Virchow mentioned in his address, the unfortunate city of Strasburg, endeared particularly to Pasteur by family ties, sustained a continuous bombardment from August 14 to September 28, which made of that old and magnificent city a pile of ruins, including its lofty cathedral. And to cap the climax, what must have been for a scientist and a patriot an unforgivable affront, is the fact that the German scientists hastened to return their French distinctions, and to sever their scientific connections with their erstwhile rivals, now become their vanquished enemies. Virchow alone indignantly refused to participate in such undignified proceedings. In recalling those unfortunate episodes, my purpose is merely to point out that what seemed to superficial or misinformed observers the vain exhibition of a pique or the bitterness of national vanity, was in reality the deep feeling of self-respect and of wounded patriotism. It would have been unworthy the name of a true patriot to accept any distinctions from the German government, on whatever ground or pretext they were proffered. And such, we confidently expect, will be the verdict of impartial history, to which we must always appeal in these controverted matters. A. DELCOURT, M.D., SR., Houma, La.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

TECHNIC OF PROCURING NORMAL HUMAN BLOOD-SERUM

To the Editor:—Can you give me the technic of procuring normal human blood-serum? I have a case of epistaxis in a child of 6 who has had general nose-bleeding for several years, sometimes on one side and sometimes the other. He has had diphtheria antitoxin three or four years ago and I have given him an injection of normal serum (horse), which was followed by rather alarming symptoms of anaphylaxis so that I feel in doubt about using further horse-serum.

J. H. FARBER, M.D., Dayton, Ohio.

ANSWER.—For obtaining sterile human serum, use either a large antitoxin syringe or a large glass pipette, depending on the quantity of blood desired. Connect to this a medium-sized needle (an antitoxin needle does very well), and sterilize, preferably by boiling. Apply a rubber constrictor not too tightly about the fleshy part of the upper arm; cleanse the skin over the antecubital fossa with alcohol (50 to 70 per cent.) and insert the needle into the most dilated vein of the fossa. With a little practice, this can be accomplished without difficulty. Withdraw the desired quantity of blood by gentle aspiration (mouth suction is necessary if a pipette be used). Before withdrawing the needle, remove constrictor and cover site of insertion with an alcohol sponge. Then pull out the needle quickly and elevate the arm for a short time to avoid the formation of a hematoma. No dressing is necessary.

To obtain the serum: (1) After removing the needle and rubber connection from the syringe, and rapidly flaming its tip, expel the blood into a sterile container. Place this on its side on ice for eight or twelve hours, after which time the serum will be found free from the clot. Or (2) expel the blood into a sterile container within which is a small coil or loop of wire. Defibrinate by means of this by simply shaking the container and centrifuge off the corpuscles, using aseptic precautions. The former method usually yields the larger quantity of serum, and is to be recommended when haste is not an object.

GRADUATE STUDY ABROAD

To the Editor:—I am seeking some information relative to a graduate course abroad. First, is a knowledge of German imperative, for instance, to pursue successfully a course of study on the eye, ear, nose and throat in Vienna or Berlin? If so, can you refer me to a suitable book from the study of which one might be able to get a fair working knowledge of the language in a few months of study at home? Can you furnish me with data relative to the courses of study—for instance, length, cost, character—whether clinical or didactic—and the best time of the year to pursue such a course.

J. B. MORTON, M.D., Ridgefarm, Ill.

ANSWER.—Practically all of these questions were taken up in detail in THE JOURNAL, April 8, 1911, p. 1056.

TECHNIC OF WASSERMANN TEST

To the Editor:—Where can I find the necessary information to perform the Wassermann test?

R. F.

ANSWER.—A description of the technic of the Wassermann serodiagnosis of syphilis may be found in THE JOURNAL, Oct. 15, 1910, p. 1308. Reference may also be made to the following article: Fleischmann and Butler: Serum Diagnosis of Syphilis, THE JOURNAL, Sept. 14, 1907, p. 934. The method may be found in the later text-books on clinical diagnosis; for instance, Anders and Boston, or Simon.

THE INTERNATIONAL MEDICAL CONGRESS

To the Editor:—Please be kind enough to advise if you have any information as to the postponement of the International Medical Congress, which is to hold its next session in London. I have seen somewhere a report that the session has been postponed to 1913.

CHARLES WOOD FASSETT, St. Joseph, Mo.

ANSWER.—The Seventeenth International Medical Congress is to be held at London, Aug. 6 to 12, 1913. The general secretary is Dr. W. P. Herringham, 40 Wimpole Street, London, W., Eng.,

The Public Service

Medical Department, U. S. Army

Changes during the week ended Sept. 30, 1911.

Wing, Franklin F., dental surgeon, ordered to proceed from Fort D. A. Russell, Wyo., to Fort Lincoln, N. D., for temporary duty.

Whaley, Arthur M., captain, detached to represent the Medical Department of the Army at the sixteenth annual session of the Seaboard Medical Association of Virginia and North Carolina, to be held at Newport News, Va., Dec. 5 to 7, 1911.

Suggs, Frank, and Hall, William E., ordered to report in person, Oct. 2, 1911, to the Army Medical School for the required course of instruction.

Stallman, George P., M.R.C., granted two months' leave of absence, to take effect about Nov. 1, 1911.

Gifin, Adolphe M., M.R.C., on arrival at San Francisco will proceed to Fort Riley, Kan., for duty.

The following named first lieutenants of the Medical Reserve Corps, recently appointed, are ordered to active duty in the service of the United States and will repair to this city and report in person on Oct. 2, 1911, to the Army Medical School for a course of instruction: Baylis, James E.; Bunker, Sidney M.; Castlen, Charles R.; Dailey, Michael A.; Hammond, Johnson F.; Meister, William B.; Tarleton, Lessen O., and Wilde, Adna G.

Medical Corps, U. S. Navy

Changes for the week ended Sept. 23, 1911.

Owens, W. D., P. A. surgeon, detached from naval hospital, Newport, R. I., and ordered to the training station at that place.

Baker, M. C., P. A. surgeon, detached from training station, Newport, R. I., and ordered to the hospital at that place.

Seaman, W., surgeon, detached from the naval station, Pensacola, Fla., and ordered to the naval disciplinary barracks, Port Royal, S. C.

Jenness, B. F., P. A. surgeon, ordered to the naval hospital, Norfolk, Va.

Kelley, H L., P. A. surgeon, detached from the navy-yard, Mare Island, Cal., and ordered to duty at the naval hospital, Norfolk, Va.

The following assistant surgeons have been detached from respective stations and ordered to the naval medical school, Washington, D. C., for instruction: R. H. Lanning, from Mare Island hospital; P. B. Ledbetter, L. Sheldon, R. F. Jones, from naval hospital, Norfolk, Va.; J. C. Parham, from naval hospital, Philadelphia: C. M. George, from naval hospital, New York.

Schier, A. R., A. A. surgeon, ordered to marine recruiting station, Kansas City, Mo.

Changes for the week ended Sept. 30, 1911.

Wheeler, W. M., surgeon, detached from the *Kansas* and ordered to the naval hospital, Norfolk, Va., for treatment.

Whiteside, L. C., P. A. surgeon, detached from the *New Jersey* and ordered to the navy-yard, Boston.

Reeves, I. S. K., P. A. surgeon, detached from the navy-yard, Philadelphia, and ordered to the *Iowa, Indiana* and *Massachusetts*.

Bacon, S., P. A. surgeon, detached from command of the naval hospital, Fort Royal, S. C., and ordered to the naval disciplinary barracks and additional duty at the naval hospital, Port Royal, S. C.

Noble, D. H., P. A. surgeon, ordered to the navy-yard, Philadelphia.

Eytinge, E. O. J., P. A. surgeon, detached from the *South Dakota* and ordered to the *Cincinnati*.

Dykes, J. R., P. A. surgeon, detached from the naval hospital, Mare Island, Cal., and ordered to the *South Dakota*.

Holeman, C. J., P. A. surgeon, ordered to the navy recruiting station, Indianapolis.

Raison, T. W., P. A. surgeon, detached from the navy recruiting station, Indianapolis, and ordered to the *Florida*.

Smith, W. B., P. A. surgeon, resignation as a passed assistant surgeon in the Navy accepted, to take effect Oct. 1, 1911.

Woodland, E. E., asst.-surgeon, detached from the *Indiana, Iowa* and *Massachusetts* and ordered to the *New Jersey*.

Cecil, A. B., asst.-surgeon, resignation as an assistant surgeon in the Navy accepted, to take effect Oct. 1, 1911.

U. S. Public Health and Marine-Hospital Service

Changes for the seven days ended Sept. 27, 1911.

Cobb, J. O., surgeon, relieved from duty at Milwaukee, Wis., and directed to proceed to Chicago and assume command of the service.

Stimpson, W. G., surgeon, granted seven days' leave of absence from Sept. 20, 1911, under paragraph 189, Service Regulations.

Nydegger, J. A., surgeon, granted one month and fourteen days' leave of absence from Sept. 24, 1911.

Mathewson, H. S., P. A. surgeon, directed to proceed to Milwaukee, Wis., and assume charge of the service.

Grubbs, S. B., P. A. surgeon, granted one month and nine days' leave of absence from Oct. 31, 1911.

Robinson, D. E., P. A. surgeon, directed to proceed to Naples, Italy, for duty.

McClintic, T. B., P. A. surgeon, directed to proceed to New Berlin, N. Y., via Albany, N. Y., on special temporary duty.

McLaughlin, A. J., P. A. surgeon, directed to proceed to certain ports on the drainage basin of lakes Michigan and Superior on special temporary duty.

Guthrie, M. C., P. A. surgeon, granted one month's leave of absence from Oct. 1, 1911.

Bean, L. C., A. A. surgeon, granted thirty days' leave of absence from Sept. 22, 1911.

Cleaves, F. H., A. A. surgeon, granted twenty days' leave of absence from Oct. 4, 1911.

Gill, S. G., A. A. surgeon, granted twenty days' leave of absence from Oct. 5, 1911.

O'Neil, A. A., A. A. surgeon, granted seven days' extension of annual leave on account of sickness, from Aug. 1, 1911.

AMERICAN ASSOCIATION OF OBSTETRICIANS AND GYNECOLOGISTS

Twenty-Fourth Annual Meeting, held in Louisville, Ky., Sept. 26-28, 1911

The President, Dr. Herman E. Hayd, Buffalo, in the Chair

Officers Elected

The following officers were elected for the ensuing year: President, Dr. Xavier O. Werder, Pittsburgh; vice-presidents, Drs. Louis Frank, Louisville, and M. A. Tate, Cincinnati; secretary, Dr. E. G. Grinkle, Cincinnati; treasurer, Dr. Herman E. Hayd, Buffalo.

The next annual meeting will be held in Toledo, Ohio, September, 1912.

Another Protest Against the Routine Use of Purgatives

Dr. Edwin Walker, Evansville: Purgatives are used entirely too often by the profession and laity. This routine use is vicious and does much harm. Is it good practice to assume that every one who requires a surgical operation likewise requires a purge? If there is fecal impaction a single purge will not remove it: several days at least will be necessary. The purgative increases the amount of fluid and also stimulates germ activity, which renders the condition less favorable for an operation on the intestine or elsewhere. Careful study of each case with more accurate diagnosis will almost do away with the habitual use of laxative drugs. The purge after a surgical operation is needed in some cases to prevent accumulation in the rectum, which is not serious but causes some discomfort. Quiet and limited diet are the causes of their failure to act, and when a liberal diet can be taken, laxatives are rarely required. The purgatives cannot remove infection. For local or general peritonitis following a laparotomy it is contraindicated. For seven years I have not given a purge before a surgical operation, except in rare cases, not 1 per cent. Patients are stronger and in a better condition for the ordeal. They have done better in every way, were more comfortable, and the abdominal cases had less pain and tympany. Gas pains were much less frequent. There were no complications which could be ascribed to the omission of the purge. Routine purgation in all surgical cases is absurd, is contrary to reason, and should be abandoned.

DISCUSSION

Dr. E. Gustav Zinke, Cincinnati: It is my practice to take a daily scant teaspoonful of epsom salts. After this is taken the bowels act naturally and satisfactorily in from fifteen to twenty minutes after breakfast. This must be associated with a mixed diet, solid food and exercise to keep the tone of the muscular structure of the colon in its natural function. Diet and exercise, with a little saline every morning before breakfast, will answer in the vast majority of cases.

Dr. H. W. Longyear, Detroit: If you give cathartics in cases of enteroptosis, it is extremely harmful. If the practitioner has a colon to deal with which is angulated and dropped down into the pelvis, if he gives the patient having that trouble cathartics he is going to do him or her, as the case may be, a vast amount of harm. He is whipping the colon into an increasing action. It is like whipping a tired horse.

Dr. William H. Humiston, Cleveland: We should distinguish between a purgative and a laxative. A purgative is an irritating medicine always, while a laxative is not. I would dislike to continue the practice of my specialty unless I could avail myself of the benefits of what I call tonic laxatives. In my abdominal operations, where the patients are in the hospital. I have the bowels thoroughly cleaned out two days before operation by the administration of a dose of castor oil. A short time before the operation a high enema is given.

Dr. Joseph M. Mathews, Louisville: I believe that six-tenths of the people are constipated. If that is true, what are we going to do to unload their bowels? What harm can a purgative or laxative do if you give it two days before an operation to unload the bowel of toxins or of fecal matter? The daily administration of a laxative is a good thing. Why not? The bowel is the sewer of the body, and why not wash it out, and what harm does it do to wash it out? You cannot simply prescribe a purgative and let these patients go. You cannot relieve them by prescribing a purgative. Many of them have pathologic conditions and in many of them there is an atonic condition of the bowel. Peristalsis is impaired and you must excite it, but it will take a long time to overcome the constipation from which some of these patients suffer. For a great many years I have given purgatives to patients two or three days before operating on them to empty the bowel. In many instances the condition of some of these patients who suffer from constipation is a surgical one, and oftentimes you are warranted with Mr. Lane and Mr. Mummery in removing the colon.

Dr. Hugo O. Pantzer, Indianapolis: I would not denounce the routine use of purgatives as strongly as the essayist does. I would emphasize one point that is not usually observed, namely, to assume that a single bowel movement for each twenty-four hours is a cause of constipation in a vast majority of cases is radically wrong. There is no organ in the body that absorbs moisture with greater avidity than does the rectum, the stomach being secondary in this regard, and that means intestinal autointoxication. If there is anything I have learned before, during and after operation, it is that the specific gravity of the urine and quantity of urea and other indications of normal elimination by the kidneys are diminished, and owing largely to constipation. There is inconvenience for the human being to go to the closet whenever he or she, as the case may be, feels the desire, and hence nature's call is frequently disregarded, but we should invariably after we feel this prompting act on it to eliminate by the rectum. It is the rectal retention of feces that does great harm.

Dr. Charles L. Bonifield, Cincinnati: It is necessary for the majority of people to have at least one evacuation of the bowels every twenty-four hours, and most people would be better off if they had more frequent evacuations. The laity use laxatives for the reason that they feel better after a free bowel movement. Many patients are constipated because the movement of the bowels is attended with more or less pain, and on account of this discomfort they put off going to stool as long as possible. In inflammatory conditions of the pelvis, I know of nothing except the prolonged use of hot douches that has so much tendency to deplete the congested pelvic organs as a free calomel purge, followed by a saline cathartic.

Dr. James F. Baldwin, Columbus: When patients come to me with constipation as a marked symptom, I send them to a professional friend who makes diseases of the alimentary canal a specialty. If after a few weeks or months he finds he cannot cure these patients, I make a modification of the Lane operation; that is, switching the ileum from the beginning of the colon to the sigmoid. I have had no deaths from this operation, no morbidity, and the operation has given me in these bad cases excellent results.

Treatment of Sliding Hernia

Dr. Walter C. G. Kirchner, St. Louis: The principal steps of my operation are to convert immovable or adherent bowel into movable bowel; to make complete reduction possible; to construct the partial or incomplete sac into a normal complete sac; to permit ligation of the sac high up beyond the ring; to enable the complete repair of the hernia to be made by one of the typical and accepted operations for hernia. The sac, after it has been isolated, is incised on either side, near and parallel to the bowel, and in this way the bowel is provided with two lateral flaps of sac. The adherent bowel having been made movable beyond the ring, the sac flaps are turned back and sewed over the denuded area of bowel, and reposition of bowel into the abdominal cavity is thus made easy. The next step lies in the partial reconstruction of the sac so that ligation or suture at the neck as in normal cases is made possible. In fifteen operations by this method, there were ten for sliding hernias of the sigmoid and five for sliding hernias of the cecum. All the cases occurred in adult male patients. In one case, the sliding hernia was through the femoral ring, there being also present a right and a left inguinal hernia. In eight cases there were double inguinal hernias, and in two instances these were complicated by femoral hernias. Undescended testicle was encountered once, and hydrocele four times. In the fifteen cases twenty-five separate herniotomies were performed, all the patients making a satisfactory recovery.

Dr. John Young Brown, St. Louis: My experience has been limited to five cases; the hernia has been on the right side. In three of them the cecum and appendix were densely adherent to the sac, making it difficult to liberate the adhesions. Dr. Kirchner's method has been of the greatest possible value to me. There is one thing in dealing with these hernias that must be carefully avoided. As the essayist has shown, the sac is incomplete. In one of my cases in endeavoring to open the sac, the bowel being attached behind, I came near getting into the bowel proper. This sliding variety of hernia is attached behind by the folds of mesentery, and by opening the sac in front, lifting up the bowel in the manner in which he has described, cutting the sac at right angles, you should see to it that the bowel is returned so that there will be no constriction of it at this point.

Angioma of the Uterus, Bladder and Broad Ligaments

Dr. Hugo O. Pantzer, Indianapolis: This was a case of racemose angioma of the uterus, bladder, urethra and broad ligament. The patient was 26 years of age, married, went through three pregnancies, two of which terminated at full term by forceps delivery. The cause of the dystocia was unknown. Both of the children were born dead. The third terminated in the second month, probably owing to the angioma. This event was followed by grave hematuria, and vesical tenesmus, and excessive metrorrhagia and menorrhagia. A fatal issue was averted by celiotomy and circumambient ligation. There was no more hematuria, except transient shortly after operating, provoked by exposure to cold and subsequent acute bronchitis and coughing. This attack of hematuria lasted two weeks, then it disappeared. Vesical irritability subsided gradually and permanently. Menstruation, which at first was profuse and prolonged, gradually became normal. One year and one-half later the patient developed suppurative appendicitis. Operation revealed a recurrence of the angioma in the broad ligament external to the previous seat of the neoplasm. Ligation was again resorted to. Examination of the patient two years after the first operation revealed the non-presence of angiomatous growth. There has been no return of the hematuria. The bladder is not irritable. Menstruation is normal. The patient's general health is good.

DISCUSSION

Dr. Walter B. Dorsett, St. Louis: I have had two cases of angioma of the uterus in which I have taken out the organ. In operating in cases in which we have a suspicion of angioma, I think the ligation of the vessels is best made *en masse*, and sew in the suture after thoroughly tying it with a No. 2 catgut ligature.

Dr. Francis Reder, St. Louis: I have met with various angiomatous conditions of the uterus in connection with fibroid tumors, where it was necessary to ablate the organ. Sometimes we meet with angioma in the broad ligaments, or the pampiniform plexus. We know that in these racemose angiomas we have destruction of the anterior uterine wall, and one finds a resisting organ of considerable density.

Dr. Charles L. Bonifield, Cincinnati: I agree that it is best to ligate the ovarian arteries *en masse*, and during the report of this case it struck me that it might have been possible and would have made the operation easier, had Dr. Pantzer by ligating the ovarian artery on the right side proceeded to ligate the internal iliac artery, as we do in some cases of extensive cancer. In this way he would have had thorough control of the arterial supply of the tumor.

ASSOCIATION OF MILITARY SURGEONS OF THE UNITED STATES

Twentieth Annual Meeting, held at Milwaukee, Wis.
Sept. 26-29, 1911

The President, Brigadier General George H. Torney, U. S. Army, in the Chair

The officers elected were named in THE JOURNAL, September 30, page 1144.

Foreign Delegates

The following delegates were present from foreign countries: France:—Surgeon Inspector Fevrier of the War Department, Paris, and Surgeon Second Class Ruotte of St. Martin's Military hospital, Paris; Argentine Republic—Dr. Jose Garrochateugui, chief surgeon of the Argentine Naval Commission in the United States and Regimental Surgeon Captain Antonio Agudo Avila, Buenos Aires; Canada—Lieutenant-Colonel Adam T. Shillington, A. M. C., Ottawa; China—Lieutenant-Colonel Hwang-I, chief surgeon, Second Division of the regular army and Lieutenant-Colonel Lu Ch'ang-en, chief surgeon Fifth Division of the regular army; Guatemala—Dr. Don Ramon Bengoechea, Guatemala City, and Great Britain—Surgeon-General Arthur William May, Royal Navy.

Entertainments

The entertainment provided by the local committee included, on Tuesday, after the public meeting, a reception and smoker at the University Club; on Wednesday, a palm garden luncheon; on Thursday, an automobile excursion around Milwaukee, with a luncheon at Whitefish Bay, and a theater party. The courtesies of the Milwaukee, University, Deutscher and Athletic clubs were extended to members and guests.

Public Meeting

The public meeting was held at the Conservatory of Music, Tuesday evening. Lieutenant-General Arthur MacArthur, U. S. Army, retired, was in the chair; Hon. Francis E. McGovern, Governor of Wisconsin, welcomed the members on behalf of the state, and Dr. Arthur J. Patek, president of the Milwaukee Medical Society, on behalf of the medical fraternity. The president delivered his annual address and the chairman of the evening made remarks regarding the overloading of the soldiers with equipment. In many of the addresses especial and affectionate mention was made of the founder of the association, a Milwaukeean, the late Col. Nicholas Senn. The foreign delegates were presented and addressed the audience, and each was presented with the insignia of the association.

Salvarsan

Surgeon Richard B. Williams, U. S. N., in his paper on "The Treatment of Syphilis with Salvarsan," described the method of administration and the results obained on board the U. S. S. *South Carolina*. He advocated the great advantage, from the standpoint of prevention, of treating all cases of syphilis by the intravenous administration of salvarsan. The mucous patches and condylomata being the most contagious ions, the method of treatment which will cause the prompt ppearance of these lesions will have great value in preting the spread of the disease. This is especially true in the military service where the use of drinking-cups or other utensils in common is more or less unavoidable.

Captain Henry J. Nichols, M.C., U. S. Army, reported the immediate clinical effects of the use of salvarsan in the Army. More than 1,200 patients were treated from January to September. In 422 of these cases the method of administration and results were as follows: intramuscular—142 cases of moderate, and 61 of severe results; intravenous—125 cases of moderate, and 60 of severe results, and subcutaneous—28 cases of moderate and 6 of severe results. By lesions the results were as follows: primary lesions—30 healed, 2 not healed; secondary eruptions—92 healed, 4 not healed; mucous patches—128 healed, 4 not healed; rupia—5 healed; iritis—10 healed; alopecia—2 healed; ulcers—14 healed, 3 not healed; joint pains—11 healed, 2 not healed; psoriasis—11 healed; headache— 4 healed, 2 not healed; gummata—7 healed; paralysis—2 healed, 1 not healed. In all 94 per cent. were healed, and 6 per cent. not healed.

Captain Mathew A. Reasoner, M.C., U. S. Army, and Lieutenant Ray W. Matson, M.R.C., U. S. Army, considered some dangers of salvarsan, based on a study of three out of eighty-three cases healed by them, from which they conclude that the literature to date would lead us to believe that the untoward effects of salvarsan noted by them need be anticipated in only a comparatively small percentage of primary and secondary cases, and need not be feared in tertiary cases, or in those to whom salvarsan may be given for other purposes; that these manifestations are syphilitic and not arsenical; that it is not a safe procedure to treat primary or secondary syphilis with salvarsan alone or with salvarsan and mercury by the mouth; that mercury in such cases should be administered hypodermically or by inunction, or both, and that patients should be kept under most careful observation; that salvarsan cannot be advised as a routine measure; that no dependence can be placed on the Wassermann test as a danger signal; that proper treatment of such cases will include forced mercurialization, and at least in the ear cases, the administration of more salvarsan; that salvarsan will come into marked disfavor with many and that considerable harm will be done on account of its present haphazard administration.

New Rôle of the Bedbug

Passed Assistant Surgeon Ransom E. Riggs, U. S. Navy, as a result of observation of epidemics of typhoid fever on board ship and in homes, where the ordinary sources of infection were absent, concludes that the majority of home epidemics of typhoid fever are due to the activity of the bedbug. This conclusion is apparently borne out by both positive and negative observations which he reports.

Panama for Troops

Passed Assistant Surgeon John G. Ziegler, U. S. Navy, reported at tour of duty with a battalion of U. S. Marines on the Isthmus of Panama, and as a result of careful observations draws the following deductions: that the isthmus, as a place of continuous habitation for not more than two years, is as healthful as the average place in the United States, but after two years there is a tendency toward physical deterioration and mental unrest which renders longer residence unadvisable; that recruits or men in their first term of enlistment bear the tropics best; that to secure contentment, means of amusement and recreation must be provided; that a proper amount of work is beneficial and favors contentment; alternating drill and police periods relieves monotony and freshens the men; that the regular ration in use in the United States is best for the men; that sunstroke and heat exhaustion are rare and harm by actinic rays mostly theory; that the khaki uniform is satisfactory, and that, outside of malaria and certain skin affections, other tropical diseases are rare on the isthmus.

Gonorrheal Prophylaxis

Assistant Surgeon Reginald B. Henry, U. S. Navy, in his brief paper on "Calomel in Gonorrheal Prophylaxis," gives the result of a six-months' experience of the use of an ointment containing 50 grams of calomel, 80 c.c. of liquid petrolatum, and 70 grams of lanolin among the men of the U. S. S. *Rainbow*, on the Asiatic station. During the period named, there were 529 admitted exposures, with four cases of gonorrhea. Of these four patients, one denied exposure and did not receive the treatment; two received treatment more than twelve hours after the exposure, so that only one possible failure of treatment remained, a percentage of .189. He finds the calomel cheap, efficacious, cleanly and non-irritating. The ordinary glass penis syringe was used for the injection of the ointment.

Passed Assistant Surgeon Allan J. McLaughlin, U. S. Public Health and Marine-Hospital Service, read a paper on "Modern Methods of Quarantine against Asiatic Cholera." The presence of cholera in Europe at this time makes this account of the methods used at quarantines in this country to prevent the entrance of the disease into the United States of particular interest to the general public. Officers of the Public Health and Marine-Hospital Service are attached to the office of the

consuls in foreign ports where cholera is prevailing, to hold under observation for five days persons coming from infected districts, before they are allowed to ship for the United States. These persons are also kept under observation by the ship's surgeon during the voyage, and he reports any cases of sickness that may occur among them. When the vessel arrives at a port in the United States, a bacteriologic examination is made of each passenger to see if any of them have cholera, or is a cholera "carrier." A "carrier" is a person who has the germ of the disease in the body, though he shows no symptoms of the disease. These people are liable to spread cholera because no one knew they had the germ in them. The bacteriologic examination reveals the fact if they are cholera carriers, and they are detained. Those who are free of the infection can now be released from quarantine in from twenty-four to forty-eight hours, instead of being held for five days as was formerly the case.

INTERNATIONAL MUNICIPAL CONGRESS AND EXPOSITION

Held in Chicago, Sept. 18 to 30, 1911

This congress, held under the auspices of the City of Chicago, Chicago Association of Commerce, Industrial Club Citizens' Association, Civic Federation, City Club United Charities, Rotary Club and Chicago Board of Underwriters, and officially approved by the United States Government, held its sessions in Chicago from September 18 to 30, inclusive. The sessions of the last three days were especially devoted to matters of municipal health, and the discussions were noteworthy in that the authors of papers and those who discussed them embodied their experiences in the particular subject, and the speeches were not, as it is usually the case, academic.

Control of Milk-Supply

After a full discussion on the control of milk-supply, the following conclusions were drawn: Cities should have testing of cows for tuberculosis; milk should be dated; icing should be required from the farm to the consumer; the sale of old milk should be prohibited; investigation of every case of contagious disease should show the milk-supply of the family, and the health department records should show the health record of every milk dealer, as regards communicable diseases among his customers. There should be a bacteriologic standard. The number of bacteria allowed should be lowest in cities where the milk is supplied by cows in the municipality; a higher number of bacteria should be allowed where the milk is hauled in wagons, and a still higher number should be allowed in cities into which milk has to be shipped by rail. Every city should use the dirt test. The method of bacteriologic examination approved was that which had been approved by the American Association of Certified Milk Commissions and the Laboratory Section of the American Public Health Association. The method of dirt examination approved was that in use in the Chicago Health Department.

Control of Contagion

A series of questions was sent to the members of the congress regarding this subject, prior to the meeting, and this gave a much higher tone to the discussion. The conclusions arrived at were: Houses should be disinfected after scarlet fever, diphtheria, tuberculosis, small-pox and anterior poliomyelitis; disease carriers should be excluded from schools; schools should not be closed on account of epidemics of scarlet fever, diphtheria and measles; vaccination should be required for all school children, diphtheria should be diagnosed on throat cultures to end quarantine, but clinical evidence should be necessary to install a quarantine, subject to revision by culture; a laboratory is necessary in the health department; typhoid fever should be made a reportable disease, and it is feasible to charge each case of contagion against the milk dealer (a committee consisting of Dr. John H. Landis, Cincinnati, and Dr. William A. Evans, Chicago, was appointed to draw up a plan of procedure); the health department should have a list of customers of each milk dealer; cases of late tuberculosis should be universally hospitalized, all small-pox should be hospitalized, and all schools should have physical and dental examinations.

Sewage, Stables and Slaughter-Houses

Questions were similarly sent to those who participated in this discussion, and the section arrived at the following conclusions: Yard privies should be allowed only in unsewered territories; the vault system should be used where there are sewers, and Stiles' boxes in unsewered localities; removal of contents of boxes should be made during the day rather than at night; removal should be by the municipality; privies should be licensed, and the ordinances should specify the type of construction and require a permit to build; the government type of closet and the government septic barrel should be required by law; stables should be licensed; manure boxes should be covered and should be impervious; the ordinances should specify the frequency of emptying at intervals of less than ten days; cow barns should be licensed; slaughter houses should be licensed; all meat, including that of calves, should be inspected and tagged, and killing of poultry should be controlled under license and should be done only in specified places.

Water Protection and Sewage

The discussion on protection of water and disposal of sewage was carried out only in part as the section adjourned to organize the Great Lakes Basin International Pure Water Association, which is noted elsewhere in this issue. Resolutions were passed, however, that no sewage or trade waste water should be allowed in lake waters untreated or uncontrolled, and that the government should take proper action to control ship sewage and the water-supply of ships.

AMERICAN ROENTGEN RAY SOCIETY

Twelfth Annual Meeting, held in Richmond, Va., Sept. 20-23, 1911

The President, DR. PERCY BROWN, Boston, in the Chair

Officers Elected

The following officers were elected to serve for the ensuing year: president, Dr. Frederick H. Baetjer, Johns Hopkins University, Baltimore; vice-presidents, Drs. H. W. Van Allen, Springfield, Mass.; G. M. Steele, Oshkosh, Wis.; J. H. Edmondson, Birmingham, Ala.; W. H. Eagar, Halifax, N. S., and Hollis E. Potter, Chicago; secretary, Dr. Henry K. Pancoast, University of Pennsylvania, Philadelphia; treasurer, Dr. Charles F. Bowen, Columbus, O.; librarian, Dr. H. W. Dachtler, Toledo, O.; executive committee, Drs. P. M. Hickey, Detroit; Arthur Holding, Albany, N. Y., and Alfred L. Gray, Richmond, Va.

Niagara Falls, N. Y. was selected as the place for holding the next annual meeting, September, 1912.

Requirements for Admission to Membership Raised

Hereafter an applicant for membership in the society must be a graduate in medicine and have been engaged actively in roentgenology for at least two years after his graduation, and he must submit a scientific paper on roentgenology to the executive committee at least six months before the next annual meeting, besides securing the recommendation of two members of the society and of at least one practicing physician or surgeon in good standing in his immediate neighborhood. The name and address of the applicant and the names and addresses of his sponsors must be published in the *Quarterly* at least twice before the next annual meeting.

Roentgenology and Its Relation to the Law

DR. PERCY BROWN, Boston: Of cases in which legal proceedings have been instituted for the alleged misuse of the Roentgen ray, occurrences are fewer than formerly. This is no doubt due to the fact that the clinical application of the ray is being relinquished by unqualified and incompetent persons. Evidence adduced by the ray is regarded much in the same light as a solar photograph would be. It is considered documentary evidence. The qualifications of the roentgenologist as a medical expert witness should be estab-

ASSOCIATION OF MILITARY SURGEONS OF THE UNITED STATES

Twentieth Annual Meeting, held at Milwaukee, Wis. Sept. 26-29, 1911

The President, Brigadier General George H. Torney, U. S. Army, in the Chair

The officers elected were named in The Journal, September 30, page 1144.

Foreign Delegates

The following delegates were present from foreign countries: France:—Surgeon Inspector Fevrier of the War Department, Paris, and Surgeon Second Class Ruotte of St. Martin's Military hospital, Paris; Argentine Republic—Dr. Jose Garrochategui, chief surgeon of the Argentine Naval Commission in the United States and Regimental Surgeon Captain Antonio Agudo Avila, Buenos Aires; Canada—Lieutenant-Colonel Adam T. Shillington, A. M. C., Ottawa; China—Lieutenant-Colonel Hwang-I, chief surgeon, Second Division of the regular army and Lieutenant-Colonel Lu Ch'ang-en, chief surgeon Fifth Division of the regular army; Guatemala—Dr. Don Ramon Bengoechea, Guatemala City, and Great Britain—Surgeon-General Arthur William May, Royal Navy.

Entertainments

The entertainment provided by the local committee included, on Tuesday, after the public meeting, a reception and smoker at the University Club; on Wednesday, a palm garden luncheon; on Thursday, an automobile excursion around Milwaukee, with a luncheon at Whitefish Bay, and a theater party. The courtesies of the Milwaukee, University, Deutscher and Athletic clubs were extended to members and guests.

Public Meeting

The public meeting was held at the Conservatory of Music, Tuesday evening. Lieutenant-General Arthur MacArthur, U. S. Army, retired, was in the chair; Hon. Francis E. McGovern, Governor of Wisconsin, welcomed the members on behalf of the state, and Dr. Arthur J. Patek, president of the Milwaukee Medical Society, on behalf of the medical fraternity. The president delivered his annual address and the chairman of the evening made remarks regarding the overloading of the soldiers with equipment. In many of the addresses especial and affectionate mention was made of the founder of the association, a Milwaukeean, the late Col. Nicholas Senn. The foreign delegates were presented and addressed the audience, and each was presented with the insignia of the association.

Salvarsan

Surgeon Richard B. Williams, U. S. N., in his paper on "The Treatment of Syphilis with Salvarsan," described the method of administration and the results obtained on board the U. S. S. *South Carolina*. He advocated the great advantage, from the standpoint of prevention, of treating all cases of syphilis by the intravenous administration of salvarsan. The mucous patches and condylomata being the most contagious lesions, the method of treatment which will cause the prompt disappearance of these lesions will have great value in preventing the spread of the disease. This is especially true in the military service where the use of drinking-cups or other utensils in common is more or less unavoidable.

Captain Henry J. Nichols, M.C., U. S. Army, reported the immediate clinical effects of the use of salvarsan in the Army. More than 1,200 patients were treated from January to September. In 422 of these cases the method of administration and results were as follows: intramuscular—142 cases of moderate, and 61 of severe results; intravenous—125 cases of moderate, and 60 of severe results, and subcutaneous—28 cases of moderate and 6 of severe results. By lesions the results were as follows: primary lesions—30 healed, 2 not healed; secondary eruptions—92 healed, 4 not healed; mucous patches—128 healed, 4 not healed; rupia—5 healed; iritis—10 healed; alopecia—2 healed; ulcers—14 healed, 3 not healed; joint pains—11 healed, 2 not healed; psoriasis—11 healed; headache—4 healed, 2 not healed; gummata—7 healed; paralysis—2 healed, 1 not healed. In all 94 per cent. were healed, and 6 per cent. not healed.

Captain Mathew A. Reasoner, M.C., U. S. Army, and Lieutenant Ray W. Matson, M.R.C., U. S. Army, considered some dangers of salvarsan, based on a study of three out of eighty-three cases healed by them, from which they conclude that the literature to date would lead us to believe that the untoward effects of salvarsan noted by them need be anticipated in only a comparatively small percentage of primary and secondary cases, and need not be feared in tertiary cases, or in those to whom salvarsan may be given for other purposes; that these manifestations are syphilitic and not arsenical; that it is not a safe procedure to treat primary or secondary syphilis with salvarsan alone or with salvarsan and mercury by the mouth; that mercury in such cases should be administered hypodermically or by inunction, or both, and that patients should be kept under most careful observation; that salvarsan cannot be advised as a routine measure; that no dependence can be placed on the Wassermann test as a danger signal; that proper treatment of such cases will include forced mercurialization, and at least in the ear cases, the administration of more salvarsan; that salvarsan will come into marked disfavor with many and that considerable harm will be done on account of its present haphazard administration.

New Rôle of the Bedbug

Passed Assistant Surgeon Ransom E. Riggs, U. S. Navy, as a result of observation of epidemics of typhoid fever on board ship and in homes, where the ordinary sources of infection were absent, concludes that the majority of home epidemics of typhoid fever are due to the activity of the bedbug. This conclusion is apparently borne out by both positive and negative observations which he reports.

Panama for Troops

Passed Assistant Surgeon John G. Ziegler, U. S. Navy, reported at tour of duty with a battalion of U. S. Marines on the Isthmus of Panama, and as a result of careful observations draws the following deductions: that the isthmus, as a place of continuous habitation for not more than two years, is as healthful as the average place in the United States, but after two years there is a tendency toward physical deterioration and mental unrest which renders longer residence unadvisable; that recruits or men in their first term of enlistment bear the tropics best; that to secure contentment, means of amusement and recreation must be provided; that a proper amount of work is beneficial and favors contentment; alternating drill and police periods relieves monotony and freshens the men; that the regular ration in use in the United States is best for the men; that sunstroke and heat exhaustion are rare and harm by actinic rays mostly theory; that the khaki uniform is satisfactory, and that, outside of malaria and certain skin affections, other tropical diseases are rare on the isthmus.

Gonorrheal Prophylaxis

Assistant Surgeon Reginald B. Henry, U. S. Navy, in his brief paper on "Calomel in Gonorrheal Prophylaxis," gives the result of a six-months' experience of the use of an ointment containing 50 grams of calomel, 80 c.c. of liquid petrolatum, and 70 grams of lanolin among the men of the U. S. S. *Rainbow*, on the Asiatic station. During the period named, there were 529 admitted exposures, with four cases of gonorrhea. Of these four patients, one denied exposure and did not receive the treatment; two received treatment more than twelve hours after the exposure, so that only one possible failure of treatment remained, a percentage of .189. He finds the calomel cheap, efficacious, cleanly and non-irritating. The ordinary glass penis syringe was used for the injection of the ointment.

Passed Assistant Surgeon Allan J. McLaughlin, U. S. Public Health and Marine-Hospital Service, read a paper on "Modern Methods of Quarantine against Asiatic Cholera." The presence of cholera in Europe at this time makes this account of the methods used at quarantines in this country to prevent the entrance of the disease into the United States of particular interest to the general public. Officers of the Public Health and Marine-Hospital Service are attached to the office of the

consuls in foreign ports where cholera is prevailing, to hold under observation for five days persons coming from infected districts, before they are allowed to ship for the United States. These persons are also kept under observation by the ship's surgeon during the voyage, and he reports any cases of sickness that may occur among them. When the vessel arrives at a port in the United States, a bacteriologic examination is made of each passenger to see if any of them have cholera, or is a cholera "carrier." A "carrier" is a person who has the germ of the disease in the body, though he shows no symptoms of the disease. These people are liable to spread cholera because no one knew they had the germ in them. The bacteriologic examination reveals the fact if they are cholera carriers, and they are detained. Those who are free of the infection can now be released from quarantine in from twenty-four to forty-eight hours, instead of being held for five days as was formerly the case.

ASSOCIATION OF MILITARY SURGEONS OF THE UNITED STATES

Twentieth Annual Meeting, held at Milwaukee, Wis. Sept. 26-29, 1911

The President, Brigadier General George H. Torney, U. S. Army, in the Chair

The officers elected were named in THE JOURNAL, September 30, page 1144.

Foreign Delegates

The following delegates were present from foreign countries: France:—Surgeon Inspector Fevrier of the War Department, Paris, and Surgeon Second Class Ruotte of St. Martin's Military hospital, Paris; Argentine Republic—Dr. Jose Garrochateugui, chief surgeon of the Argentine Naval Commission in the United States and Regimental Surgeon Captain Antonio Agudo Avila, Buenos Aires; Canada—Lieutenant-Colonel Adam T. Shillington, A. M. C., Ottawa; China—Lieutenant-Colonel Hwang-I, chief surgeon, Second Division of the regular army and Lieutenant-Colonel Lu Ch'ang-en, chief surgeon Fifth Division of the regular army; Guatemala—Dr. Don Ramon Bengoechea, Guatemala City, and Great Britain—Surgeon-General Arthur William May, Royal Navy.

Entertainments

The entertainment provided by the local committee included, on Tuesday, after the public meeting, a reception and smoker at the University Club; on Wednesday, a palm garden luncheon; on Thursday, an automobile excursion around Milwaukee, with a luncheon at Whitefish Bay, and a theater party. The courtesies of the Milwaukee, University, Deutscher and Athletic clubs were extended to members and guests.

Public Meeting

The public meeting was held at the Conservatory of Music, Tuesday evening. Lieutenant-General Arthur MacArthur, U. S. Army, retired, was in the chair; Hon. Francis E. McGovern, Governor of Wisconsin, welcomed the members on behalf of the state, and Dr. Arthur J. Patek, president of the Milwaukee Medical Society, on behalf of the medical fraternity. The president delivered his annual address and the chairman of the evening made remarks regarding the overloading of the soldiers with equipment. In many of the addresses especial and affectionate mention was made of the founder of the association, a Milwaukeean, the late Col. Nicholas Senn. The foreign delegates were presented and addressed the audience, and each was presented with the insignia of the association.

Salvarsan

Surgeon Richard B. Williams, U. S. N., in his paper on "The Treatment of Syphilis with Salvarsan," described the method of administration and the results obained on board the U. S. S. *South Carolina*. He advocated the great advantage, from the standpoint of prevention, of treating all cases of syphilis by the intravenous administration of salvarsan. The mucous patches and condylomata being the most contagious lesions, the method of treatment which will cause the prompt disappearance of these lesions will have great value in preventing the spread of the disease. This is especially true in the military service where the use of drinking-cups or other utensils in common is more or less unavoidable.

Captain Henry J. Nichols, M.C., U. S. Army, reported the immediate clinical effects of the use of salvarsan in the Army. More than 1,200 patients were treated from January to September. In 422 of these cases the method of administration and results were as follows: intramuscular—142 cases of moderate, and 61 of severe results; intravenous—125 cases of moderate, and 60 of severe results, and subcutaneous—28 cases of moderate and 6 of severe results. By lesions the results were as follows: primary lesions—30 healed, 2 not healed; secondary eruptions—92 healed, 4 not healed; mucous patches—128 healed, 4 not healed; rupia—5 healed; iritis—10 healed; alopecia—2 healed; ulcers—14 healed, 3 not healed; joint pains—11 healed, 2 not healed; psoriasis—11 healed; headache—4 healed, 2 not healed; gummata—7 healed; paralysis—2 healed, 1 not healed. In all 94 per cent. were healed, and 6 per cent. not healed.

Captain Mathew A. Reasoner, M.C., U. S. Army, and Lieutenant Ray W. Matson, M.R.C., U. S. Army, considered some dangers of salvarsan, based on a study of three out of eighty-three cases healed by them, from which they conclude that the literature to date would lead us to believe that the untoward effects of salvarsan noted by them need be anticipated in only a comparatively small percentage of primary and secondary cases, and need not be feared in tertiary cases, or in those to whom salvarsan may be given for other purposes; that these manifestations are syphilitic and not arsenical; that it is not a safe procedure to treat primary or secondary syphilis with salvarsan alone or with salvarsan and mercury by the mouth; that mercury in such cases should be administered hypodermically or by inunction, or both, and that patients should be kept under most careful observation; that salvarsan cannot be advised as a routine measure; that no dependence can be placed on the Wassermann test as a danger signal; that proper treatment of such cases will include forced mercurialization, and at least in the ear cases, administration of more salvarsan: that salvarsan will co into marked disfavor with many and that considerable ha will be done on account of its present haphazard administr tion.

New Rôle of the Bedbug

Passed Assistant Surgeon Ransom E. Riggs, U. S. Navy, as a result of observation of epidemics of typhoid fever on board ship and in homes, where the ordinary sources of infection were absent, concludes that the majority of home epidemics of typhoid fever are due to the activity of the bedbug. This conclusion is apparently borne out by both positive and negative observations which he reports.

Panama for Troops

Passed Assistant Surgeon John G. Ziegler, U. S. Navy, reported at tour of duty with a battalion of U. S. Marines on the Isthmus of Panama, and as a result of careful observations draws the following deductions: that the isthmus, as a place of continuous habitation for not more than two years, is as healthful as the average place in the United States, but after two years there is a tendency toward physical deterioration and mental unrest which renders longer residence unadvisable; that recruits or men in their first term of enlistment bear the tropics best; that to secure contentment, means of amusement and recreation must be provided; that a proper amount of work is beneficial and favors contentment; alternating drill and police periods relieves monotony and freshens the men; that the regular ration in use in the United States is best for the men; that sunstroke and heat exhaustion are rare and harm by actinic rays mostly theory; that the khaki uniform is satisfactory, and that, outside of malaria and certain skin affections, other tropical diseases are rare on the isthmus.

Gonorrheal Prophylaxis

Assistant Surgeon Reginald B. Henry, U. S. Navy, in his brief paper on "Calomel in Gonorrheal Prophylaxis," gives the result of a six-months' experience of the use of an ointment containing 50 grams of calomel, 80 c.c. of liquid petrolatum, and 70 grams of lanolin among the men of the U. S. S. *Rainbow*, on the Asiatic station. During the period named, there were 529 admitted exposures, with four cases of gonorrhea. Of these four patients, one denied exposure and did not receive the treatment; two received treatment more than twelve hours after the exposure, so that only one possible failure of treatment remained, a percentage of .189. He finds the calomel cheap, efficacious, cleanly and non-irritating. The ordinary glass penis syringe was used for the injection of the ointment.

Passed Assistant Surgeon Allan J. McLaughlin, U. S. Public Health and Marine-Hospital Service, read a paper on "Modern Methods of Quarantine against Asiatic Cholera." The presence of cholera in Europe at this time makes this account of the methods used at quarantines in this country to prevent the entrance of the disease into the United States of particular interest to the general public. Officers of the Public Health and Marine-Hospital Service are attached to the office of the

consuls in foreign ports where cholera is prevailing, to hold under observation for five days persons coming from infected districts, before they are allowed to ship for the United States. These persons are also kept under observation by the ship's surgeon during the voyage, and he reports any cases of sickness that may occur among them. When the vessel arrives at a port in the United States, a bacteriologic examination is made of each passenger to see if any of them have cholera, or is a cholera "carrier." A "carrier" is a person who has the germ of the disease in the body, though he shows no symptoms of the disease. These people are liable to spread cholera because no one knew they had the germ in them. The bacteriologic examination reveals the fact if they are cholera carriers, and they are detained. Those who are free of the infection can now be released from quarantine in from twenty-four to forty-eight hours, instead of being held for five days as was formerly the case.

INTERNATIONAL MUNICIPAL CONGRESS AND EXPOSITION

Held in Chicago, Sept. 18 to 30, 1911

This congress, held under the auspices of the City of Chicago, Chicago Association of Commerce, Industrial Club Citizens' Association, Civic Federation, City Club United Charities, Rotary Club and Chicago Board of Underwriters, and officially approved by the United States Government, held its sessions in Chicago from September 18 to 30, inclusive. The sessions of the last three days were especially devoted to matters of municipal health, and the discussions were noteworthy in that the authors of papers and those who discussed them embodied their experiences in the particular subject, and the speeches were not, as it is usually the case, academic.

Control of Milk-Supply

After a full discussion on the control of milk-supply, the following conclusions were drawn: Cities should have testing of cows for tuberculosis; milk should be dated; icing should be required from the farm to the consumer; the sale of old milk should be prohibited; investigation of every case of contagious disease should show the milk-supply of the family, and the health department records should show the health record of every milk dealer, as regards communicable diseases among his customers. There should be a bacteriologic standard. The number of bacteria allowed should be lowest in cities where the milk is supplied by cows in the municipality; a higher number of bacteria should be allowed where the milk is hauled in wagons, and a still higher number should be allowed in cities into which milk has to be shipped by rail. Every city should use the dirt test. The method of bacteriologic examination approved was that which had been approved by the American Association of Certified Milk Commissions and the Laboratory Section of the American Public Health Association. The method of dirt examination approved was that in use in the Chicago Health Department.

Control of Contagion

A series of questions was sent to the members of the congress regarding this subject, prior to the meeting, and this gave a much higher tone to the discussion. The conclusions arrived at were: Houses should be disinfected after scarlet fever, diphtheria, tuberculosis, small-pox and anterior poliomyelitis; disease carriers should be excluded from schools: schools should not be closed on account of epidemics of scarlet fever, diphtheria and measles; vaccination should be required for all school children, diphtheria should be diagnosed on throat cultures to end quarantine, but clinical evidence should be necessary to install a quarantine, subject to revision by culture; a laboratory is necessary in the health department; typhoid fever should be made a reportable disease, and it is feasible to charge each case of contagion against the milk dealer (a committee consisting of Dr. John H. Landis, Cincinnati, and Dr. William A. Evans, Chicago, was appointed to draw up a plan of procedure); the health department should have a list of customers of each milk dealer; cases of late tuberculosis should be universally hospitalized, all small-pox should be hospitalized, and all schools should have physical and dental examinations.

Sewage, Stables and Slaughter-Houses

Questions were similarly sent to those who participated in this discussion, and the section arrived at the following conclusions: Yard privies should be allowed only in unsewered territories; the vault system should be used where there are sewers, and Stiles' boxes in unsewered localities; removal of contents of boxes should be made during the day rather than at night; removal should be by the municipality; privies should be licensed, and the ordinances should specify the type of construction and require a permit to build; the government type of closet and the government septic barrel should be required by law; stables should be licensed; manure boxes should be covered and should be impervious; the ordinances should specify the frequency of emptying at intervals of less than ten days; cow barns should be licensed; slaughter houses should be licensed; all meat, including that of calves, should be inspected and tagged, and killing of poultry should be controlled under license and should be done only in specified places.

Water Protection and Sewage

The discussion on protection of water and disposal of sewage was carried out only in part as the section adjourned to organize the Great Lakes Basin International Pure Water Association, which is noted elsewhere in this issue. Resolutions were passed, however, that no sewage or trade waste water should be allowed in lake waters untreated or uncontrolled, and that the government should take proper action to control ship sewage and the water-supply of ships.

(To be concluded)

AMERICAN ROENTGEN RAY SOCIETY

Twelfth Annual Meeting, held in Richmond, Va., Sept. 20-23, 1911

The President, Dr. Percy Brown, Boston, in the Chair

Officers Elected

The following officers were elected to serve for the ensuing year: president, Dr. Frederick H. Baetjer, Johns Hopkins University, Baltimore; vice-presidents, Drs. H. W. Van Allen, Springfield, Mass.; G. M. Steele, Oshkosh, Wis.; J. H. Edmondson, Birmingham, Ala.; W. H. Eagar, Halifax, N. S., and Hollis E. Potter, Chicago; secretary, Dr. Henry K. Pancoast, University of Pennsylvania, Philadelphia; treasurer, Dr. Charles F. Bowen, Columbus, O.; librarian, Dr. H. W. Dachtler, Toledo, O.; executive committee, Drs. P. M. Hickey, Detroit; Arthur Holding, Albany, N. Y., and Alfred L. Gray, Richmond, Va.

Niagara Falls, N. Y. was selected as the place for holding the next annual meeting, September, 1912.

Requirements for Admission to Membership Raised

Hereafter an applicant for membership in the society must be a graduate in medicine and have been engaged actively in roentgenology for at least two years after his graduation, and he must submit a scientific paper on roentgenology to the executive committee at least six months before the next annual meeting, besides securing the recommendation of two members of the society and of at least one practicing physician or surgeon in good standing in his immediate neighborhood. The name and address of the applicant and the names and addresses of his sponsors must be published in the *Quarterly* at least twice before the next annual meeting.

Roentgenology and Its Relation to the Law

Dr. Percy Brown, Boston: Of cases in which legal proceedings have been instituted for the alleged misuse of the Roentgen ray, occurrences are fewer than formerly. This is no doubt due to the fact that the clinical application of the ray is being relinquished by unqualified and incompetent persons. Evidence adduced by the ray is regarded much in the same light as a solar photograph would be. It is considered documentary evidence. The qualifications of the roentgenologist as a medical expert witness should be estab-

lished; his recognition in his own community and in a recognized society of his colleagues should be ascertained and certified to. In court an absolutely neutral attitude should place him beyond reproach. His evidence should be prepared carefully and with attention to detail. Except for purposes of his own identification, all records should be marked in the presence of the court at the time they are admitted as evidence. Unless his evidence can rest on the framework of his professional qualifications as an expert, it will lose weight and even be discarded.

Roentgen Ray in Hypertrophied Prostate

Dr. James W. Hunter, Norfolk, Va.: The ideal treatment in hypertrophied prostate is radical removal of the gland. In the hands of expert operators who select their cases the results are excellent; in the hands of the occasional operator or the inexpert, the mortality is high. In selected cases roentgenotherapy is of great value. When the increase in size is due largely to overgrowth of the epithelium, the Roentgen ray will quickly diminish the size of the gland, but not so if there is much increase in the amount of connective tissue. The results from the treatment depend largely on the histologic structure. Massage is indicated as an adjuvant. The mortality is *nil*.

DISCUSSION

Dr. Hollis E. Potter, Chicago: It is not easy to differentiate by digital examination between a fibrous, muscular or epithelial enlargement of the prostate; but by raying the testicles as well as the prostate, we can produce an effect analogous to that produced by raying the ovaries and uterus, reducing the size of the gland considerably. I have, however, seen few good results follow the Roentgen treatment of hypertrophied prostate.

Dr. George E. Pfahler, Philadelphia: Sufficiently good results have been obtained by careful workers to cause us to consider this treatment of hypertrophied prostate in otherwise hopeless cases, and to justify its use. It is especially indicated in the case of old or decrepit patients who cannot stand an operation, and in patients in whom the question of procreation is not to be considered.

Postoperative Roentgenization in Cancer

Dr. Clarence E. Skinner, New Haven, Conn.: The Roentgen ray has demonstrated that it exhibits a powerful curative influence on malignant degeneration, hence its routine use as a postablative measure will increase greatly the number of curative cases. It is impossible to tell beforehand which cases will need roentgenization and which will not, or which cases will respond happily and which will not respond at all, hence the only way to be sure of treating all cases that will need it and that will respond, is to treat all cancer cases. Roentgenization should be commenced as soon after operation as is consistent with the safety of the tissues involved in the operation wound and before recurrence has had an opportunity to manifest itself. The application of the ray should be entrusted only to those who are competent and experienced. These patients should not be rayed before operation because the effect of vigorous radiation of the malignant growth is to produce a certain amount of systemic toxemia, which has been known to be severe enough to kill the patient. Such radiation also often leads to an increase in fibrous tissue, leading to such confusion of tissue and obliteration of normal tissue distinctions and relations as to embarrass the operator. Furthermore, effective pre-operative radiation means delaying the operation unnecessarily.

DISCUSSION

Dr. George E. Pfahler, Philadelphia: There is no doubt of the good effect of the Roentgen ray in these cases. Unfortunately, the average surgeon will only refer those cases in which there is bound to be a recurrence and in which, therefore, little good can be effected. Ante-operative radiation is not advisable as a routine procedure, although I do not believe that it is as harmful as Dr. Skinner seems to think. I have not seen any evidence of toxemia. However, postoperative treatment is certainly advisable and effective.

Dr. J. H. Edmondson, Birmingham, Ala.: Is it not advisable to excise nodular recurrences in the scar before beginning the Roentgen treatment?

Dr. W. H. Eagar, Halifax, N. S.: We undoubtedly get a tremendous degree of toxemia from pre-operative treatment, but early and effective radiation following the operation is the proper thing. Unfortunately these patients are not referred to us until after recurrences have appeared.

Dr. J. H. Selby, Rochester, Minn.: I believe that surgeons are becoming aware of the value of immediate postoperative roentgenization in these cases, because when the treatment is carried out by an expert who cooperates with the surgeon the results are always good.

Dr. Frederick H. Baetjer, Baltimore: The pre-operative treatment of such patients is criminal. The Roentgen ray is stimulative and destructive, and any such form of treatment of a malignant process is wrong. We must not do anything to increase cell division because that increases the possibility of metastases occurring. A carcinoma that is operable is a surgical condition and not to be treated by the Roentgen ray. So far as postoperative treatment is concerned I agree with the other speakers. I believe, however, that in many cases where enlarged glands are broken down by radiation these glands are not carcinomatous but simply enlarged as the result of an inflammatory condition or reaction.

Carcinomatosis of Bones Secondary to Growth in Some Epithelial Organ

Dr. Russell H. Boggs, Pittsburgh: Carcinoma of the bone is always secondary. As a rule, it is not recognized until fracture occurs. It may be secondary to cancer situated in any part of the body, and any bone may be involved, although it is usually a long bone. It is slow-growing and gives rise to symptoms which frequently lead to a diagnosis of rheumatism.

DISCUSSION

Dr. Henry K. Pancoast, Philadelphia: In one case I had there occurred a metastasis in the femur just below the great trochanter eight years after the removal of a cancer of the breast. In another case a similar metastasis occurred following the removal of a bronchial cyst which had undergone carcinomatous degeneration. I have also seen metastases in the vertebræ.

Dr. George E. Pfahler, Philadelphia: Patients who complain of vague rheumatic pains after operations for the removal of malignant growths often are later found to be suffering from a bone metastasis, and unless fracture of the bone occurs, the condition is not detected. A patient with recurrent carcinoma and metastases in the breast fell and broke his arm. I made a roentgenogram and found metastases not only in that arm, but in the other arm, and in one femur. Another patient fell and injured her hip. The roentgenogram showed distinctly a metastatic carcinoma and on careful examination the original tumor was discovered in the breast, a small cancer, of whose existence the patient was not aware.

Dr. Frederick H. Baetjer, Baltimore: I have seen quite a number of cases of metastasis of cancer in bone. Four of these were in the femur following a primary cancer of the breast. The femora and the spine are the most frequent seats of cancerous metastases. I have had two cases of cancer of the humerus secondary to cancer of the stomach, and one case secondary to cancer of the bladder. In another case there were extensive metastases in the femur and in the scapula secondary to the breast cancer.

Dr. George H. Stover, Denver: In four cases of metastatic cancer of bones which I saw the primary tumor was situated in the breast. In one case the condition was not discovered until a fracture of the bone occurred twenty-five years after the removal of the breast cancer.

Dr. John H. Selby, Rochester, Minn.: Following the removal of a tumor of the kidney, a patient developed sciatic-like pains. I found complete destruction of the pubes extending to the acetabulum. I have seen several cases of bone metastasis following cancer in distant parts of the body.

Medical Economics

THIS DEPARTMENT EMBODIES THE SUBJECTS OF POSTGRADUATE WORK, CONTRACT PRACTICE, LEGISLATION, MEDICAL DEFENSE, AND OTHER MEDICOLEGAL AND ECONOMIC QUESTIONS OF INTEREST TO PHYSICIANS

MEN AND HOGS

Under this title, the Fresno (Cal.) *Republican* recently discussed health reforms, following Dr. McCormack's visit to that city. This editorial is a most rational and discriminating discussion on the unconscious attitude of the majority of people to health matters and is deserving of careful reading and consideration.

"Dr. McCormack, in his lecture last night, referred to the incongruity of the American government spending millions to eradicate the diseases of pigs and potatoes, and nothing to eradicate the diseases of men.

"The contrast is indeed somewhat startling, but the explanation is easy. For one thing, pigs and potatoes cost money, while men are cheap. Perhaps still more important, there are 'systems' or 'schools' with regard to the diseases of men, but none with regard to the diseases of animals or plants. Nobody ever offered to cure hog cholera by reading sermons to the swine, nor undertook to eradicate potato blight by spilling 1 drop of potato soup into the river from which the irrigation water came. Nobody ever tried to cure the boll weevil in cotton by untwisting some rootlets that had become entangled. Nobody ever undertook to argue the chinch bug out of existence by proving that it was inconsistent with the divine plan. And nobody would be listened to with seriousness if he proposed these things. We have passed the days of fetichism and witchcraft, in dealing with corn and cattle, and we accept scientific investigation as the way to find out scientific truth about them.

"But when it comes to human diseases, exactly these things are preached by the expounders of various sects of healing, and are devoutly believed by a multitude of adherents of those sects. The pear blight or the Anaheim disease we know to be facts, and when the scientists tell us they have not yet found the cause or cure of those diseases, we supply them with the money for further investigations instead of seeking some new magician who says he can cure them by incantations. But human diseases we know are mysteries; human physicians we know are magicians; and human healing we know to be a matter of faith, expressed in various creeds, each true to those that profess it and false to all others.

"This is a government by the people, and the people, in vast multitudes, believe these things. What matters it then that the divine penalty of sanitary heresy is death? We have fought out freedom of faith in theology, where the penalty of error is hell. Shall we not protect it in pathology, where the penalty of error is merely death? Is not the liberty of people to cure small-pox by abacadabral signs more precious than the lives of the citizens? Therefore, by what right shall the government establish a department for the scientific investigation and control of public health problems, when multitudes of people prefer faith in a creed to the collected results of scientific knowledge?

"This is the argument. It is illogical and ridiculous, but millions of entirely serious people believe it, and, so long as they do the right of a free government to care for human health will be abridged. Doubtless if hogs had votes, there would be similar limits on the protection of hogs. Any pig would prefer cholera swill to a protective inoculation. We respect the liberty of humans, but not of hogs, to indulge such preferences."

"AT HOW MANY RABBITS OR GUINEA PIGS DO YOU VALUE: YOUR WIFE, YOUR HUSBAND OR YOUR CHILD?"

POSTGRADUATE COURSE FOR COUNTY SOCIETIES

[NOTE.—The pamphlets containing the outline of the postgraduate study course for county societies for the coming year are ready for distribution. Secretaries of county societies can secure supplies by writing to the Secretary, Council on Health and Public Instruction, American Medical Association, 535 Dearborn Ave., Chicago.]

General Subject for the Month: Surgery of the Brain

Second Month—First Weekly Meeting

ANATOMY OF SKULL: DEMONSTRATE SPECIMEN

VERTEX OF SKULL: External surface—boundaries, bones included, sutures, glabella, bregma, inion.

Internal surface—shape, surface markings.

BASE OF SKULL: Internal surface, fossæ.

Anterior Fossa: Shape, boundaries, bones, portion of brain, foramen cæcum, olfactory groove, ethmoidal foramina.

Middle Fossa: Boundaries, bones, portion of brain, optic foramen, sella turcica, cavernous groove, sphenoidal fissure, foramen ovale, foramen spinosum, foramen lacerum medium, anterior surface of petrous portion of temporal.

Posterior Fossa: Shape, boundaries, bones, portion of brain, foramen magnum, jugular foramen, internal auditory meatus, inferior occipital fossæ.

EXTERNAL SURFACE: Boundaries, occipital, temporal, sphenoid and ethmoid bones, articular surfaces, orifices of foramina mentioned above, stylo-mastoid foramen. Roof and apex of orbit.

LATERAL REGION: Boundaries, bones.

Temporal Fossa: Boundaries, sutures, stephanion, pterion.

Mastoid Portion: Bones, mastoid process, auditory meatus.

Zygomatic Fossa: Spheno-maxillary fossa.

ANATOMY OF BRAIN

MEMBRANES OF BRAINS: (1) Dura mater; (2) arachnoid; (3) pia mater.

PORTIONS OF BRAIN: Medulla, pons Varolii, cerebellum, midbrain, cerebrum.

VENTRICLES: Lateral, third, fourth, foramen of Magendie, aqueduct of Sylvius, communications, contents.

Distribution of Gray and White Matter: (1) in the bulb; (2) in the pons; (3) in the midbrain; (4) in the cerebrum; (5) in the cerebellum.

Blood-Vessels: (a) To meninges; (b) to pia and brain substance. Circle of Willis and branches. Charcot's "artery of cerebral hemorrhage." Cerebral veins and sinuses.

Physiology of the Brain

Sensori-Motor Area: Fissure of Rolando, anterior and posterior central gyri, paracentral lobule, operculum, third frontal gyrus. Leg, arm and head regions. Hemiplegia, monospasm, Jacksonian epilepsy. Muscular sense, parietal lobes. Pressure, pain, temperature, sense.

Speech Areas: Sylvian fissure, third frontal convolution, motor aphasia. First and second temporal convolutions, sensory aphasia. Visual speech area, lower parietal. Right- and left-handed persons.

Sight Area: Occipital lobes, hemianopsia. Two visual centers.

Sound Area: First and second temporal convolutions.

Psychic Centers: Frontal lobes. "Silent areas."

Functions of Cerebellum: Coordination, psychical functions, location of function.

Functions of Medulla: Respiratory and circulatory centers

Cerebral Topography: Fissure of Rolando, fissure of Sylvius. Horsley's method. Krönlein's method, Chiene's method.

REFERENCE BOOKS FOR THE SECOND MONTH

Keen's Surgery, vols. ii and iii.
Bryant and Buck: Surgery.
Ballance: Surgery of the Brain.
Horsley: Brain and Spinal Cord.
Krause: Surgery of the Brain.
Phelps: Injuries of the Brain and Its Membranes.
Starr: Brain Surgery.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

Georgia: Regular, Atlanta, October 10. Sec., Dr. C. T. Nolan, Marietta. Homeopathic, Atlanta, October 10. Sec., Dr. R. E. Hinman, 106½ Whitehall Street.

Illinois: Coliseum Annex, Chicago, October 26-28. Sec., Dr. J. A. Egan, Springfield.

Kansas: National Hotel, Topeka, October 10-12. Sec., Dr. H. A. Dykes, Lebanon.

Louisiana: New Orleans, October 19-21. Sec., Dr. A. B. Brown, 108 Baronne Street.

Michigan: Legislative Bldg., Lansing, October 10-12. Sec., Dr. B. D. Harison, 504 Washington Arcade, Detroit.

Mississippi: State Capitol, Jackson, October 10-11. Sec., Dr S. H. McLean.

New Jersey: The State Capitol, Trenton, October 17-18. Sec., Dr. H. G. Norton, 429 E. State Street.

New Mexico: The Capitol, Santa Fe, October 9-10. Sec., Dr J. A. Massie.

Oklahoma: Muskogee, October 10. Sec., Dr. John W. Duke, Guthrie.

Wyoming: Riverton, October 9-11. Sec., Dr. A. B. Tonkin.

Maryland June Report

Dr. J. McPherson Scott, secretary of the Maryland Board of Medical Examiners, reports the written examination held at Baltimore, June 20, 1911. The number of subjects examined in was 9; total number of questions asked, 90; percentage required to pass, 75. The total number of candidates examined was 152, of whom 130 passed and 22 failed. Sixteen candidates were licensed through reciprocity, 1 by special examination, and 1 under the exemption clause. The following colleges were represented:

* Reexamined.

The questions asked were as follows:

ANATOMY

1. Name varieties of cartilage. 2. Describe briefly two varieties named. 3. Describe the clavicle. 4. Describe the hip joint. 5. What arteries supply the heart with blood and where do they originate? 6. Give general description of testicles. 7. Describe the pericardium. 8. What are the parathyroid bodies? 9. Name the twelve pairs of cranial nerves. 10. Name principal muscles of the back.

PATHOLOGY

1. Mention a cause for each of the following conditions: edema of one leg, edema of both legs, edema of one arm, ascites, edema of the lungs, hydrothorax. 2. What is meant by the term compensation as used in heart diseases? By broken compensation? Trace the course of events depending on the latter condition. 3. Mention at least five diseases that are transmitted by insects. Name the carriers and the method by which the infection is introduced. 4. What is a cyst? Mention two forms of cyst that are commonly met with, and explain their causation. What is meant by the term encysted? 5. Describe briefly the gross and microscopic appearances of an atrophic cirrhotic liver. Mention the pathologic changes inherent to this condition. 6. Describe the formation of scar tissue and mention its principal characteristics. 7. What is the Widal reaction? 8. What is an aneurysm? Describe the formation of an aneurysm of the aorta. 9. How would you demonstrate the presence of bacteria in milk? How would you estimate the number in a cubic centimeter of milk? 10. What are the essential lesions of scarlet fever? What means would you use to prevent the spreading of the contagion in this disease?

CHEMISTRY

1. Explain the following terms: (a) Molecular weight, (b) precipitate, (c) valence, (d) oxidation, (e) efflorescence. 2. Give the general characteristics of acids. Define monobasic, dibasic and tribasic acid, and give an example of each. 3. Give the chemical names and composition of "calomel" and "corrosive sublimate." How may one be distinguished from the other? 4. Give one chemical antidote for each of the following: (a) Nitric acid, (b) oxalic acid, (c) arsenic trioxid, (d) morphine sulphate. 5. Give (a) one chemical test for albumin in urine, and (b) one test for sugar in urine. 6. What is the normal reaction to litmus paper of (a) blood, (b) saliva, (c) succus gastricus, (d) succus entericus, and (e) feces. 7. Give the chemical formula of each of the following: (a) Sulphuric acid, (b) hydrochloric acid,
(d) epsom salt, (c) ammonia water,
tion, (b) calorie, (c) indicanuria, (d)
9. Give the chemical formula and properties of hydrogen peroxid. 10. Complete the following equations: $Na_2CO_3 + HCl =$
$K + H_2O =$ $CO_2 + Ca(OH)_2 =$ $Mg + H_2SO_4 =$
$CuO + 2HNO_3 =$

PHYSIOLOGY

1. Name and locate the glands of the small intestines. 2. (a) Describe the normal pulse, its variations in infancy, youth and old age; (b) How does the pulse rate compare with respiration? 3. Where in the body is each of the following found and what the function of each: pepsin, trypsin, glycogen, ptyalin and synovia? 4. What is meant by the vasomotor nervous system? 5. What is meant by blood-pressure and how estimated? (b) What are some

of the causes altering blood-pressure? (c) How does the weight of the entire amount of blood in the body compare with the weight of the body? 6. Give functions of spinal cord. 7. What is accomplished physiologically by the portal circulation? 8. Describe briefly the functions of the pneumogastric nerve. 9. Through what three main channels is water lost from the body? 10. Describe the effect of strychnin on the central nervous system.

THERAPEUTICS

1. Define chemical incompatibility. Give three illustrations and write a prescription showing it. 2. Define pharmaceutical incompatibility. Give three illustrations and write a prescription showing it. 3. Give physiologic action of glonoinum and indications for its use. 4. Describe the indications for use of carbohydrates. Illustrate their use and name six. 5. Give the therapeutics of arsenous acid; symptoms of arsenical poisoning and antidote. 6. Give the therapeutics of acid hydrocyanic; manifestation of poisoning and antidote. 7. Write a prescription in Latin, without abbreviations, containing four liquid ingredients; state conditions for which it is intended and give directions for its use. 8. Write a prescription in Latin, without abbreviations, containing three ingredients in powder; state conditions for which it is intended and give directions for its use. 9. State briefly the therapeutics of nux vomica. 10. State briefly the therapeutics of thyroid extract and adrenal extract.

MATERIA MEDICA

1. (a) Plumbum—give five preparations. (b) The treatment in case of poisoning. 2. (a) Codein, heroin, dionin, and peronin—from what prepared? Dose of each. (b) To what class of drugs do chloral hydrate, sulphonal, trional, veronal and the bromids belong? Average dose of each. 3. (a) Define tinctures and extracts. (b) What is meant by incompatibility in medicines? Name some incompatibles. 4. Write a prescription containing in pill form iron, quinin, arsenic and strychnin, using the official terms in full. 5. To what class of drugs do camphor, asafetida, valerian, compound spirits of ether, musk and viburnum prunifolium belong? Give the average dose of each. 6. To what class of drugs do acetanilid, antipyrin, phenacetin, quinin, aconite, guaiacol belong. The average dose of each. 7. (a) Name five vegetable astringents. (b) Name five mineral astringents. (c) Name three diuretics. (d) What are expectorants and into what two classes are they divided. Name some of each. 8. Give the composition of black wash, brown mixture and compound cathartic pill. 9. Write a prescription for a child five years old, containing paregoric, subnitrate of bismuth, prepared chalk, using in full the official names. 10. Define materia medica. What is meant by U. S. Pharmacopeia?

PRACTICE

1. Define (a) Kernig's sign, (b) tachycardia, (c) cholecystitis, (d) myxedema, (e) urticaria. 2. Define (a) Grocco's sign, (b) tabes dorsalis, (c) herpes zoster, (d) rubella, (e) hydronephrosis. 3. Differentiate variola and varicella. 4. Cancer and ulcer of the stomach. 5. Spasmodic and membranous croup. 6. Coma of alcohol, uremia and cerebral hemorrhage. 7. Give treatment of acute chorea. 8. Give treatment of chronic nephritis. 9. Give treatment of ulcerative stomatitis. 10. Give diagnosis and treatment of intestinal perforation in typhoid fever.

SURGERY

1. What is trachoma? Give signs and symptoms. 2. Give the definitions of toxemia, septicemia, pyemia. 3. Give strength and dose of solution of cocain for local anesthesia, its indications and dangers. 4. Name the general anesthetics employed in surgical cases. 5. Surgical shock: Give physiology, etiology, symptoms, diagnosis and treatment. 6. Describe a simple manner of testing the hearing and its expression by fractional formula. 7. Give the differential diagnosis between chronic appendicitis and gall-stones. 8. Name some causes, symptoms and treatment of caries. 9. Give the secondary symptoms of acquired syphilis. 10. Describe the operation of thoracotomy (resection of ribs) and give the indications for the same.

OBSTETRICS

1. Describe the pelvis joints and their relation to labor and delivery. 3. What is a corpus luteum? 3. What is the cause of hyperemesis gravidarum and the clinical features and the treatment of the condition? 4. Describe in detail the symptoms of extra-uterine pregnancy. 5. Give the diagnosis and management of a breech presentation. What are the dangers to the child? 6. Describe the application of forceps to the fetal head. 7. How would you manage a case of primary post-partum hemorrhage? 8. How would you treat a case of complete prolapsus uteri? 9. Give the treatment of mastitis. 10. Ophthalmia neonatorum. Give prophylaxis and treatment.

Georgia May Report

Dr. C. T. Nolan, secretary of the Regular Board of Medical Examiners of Georgia, reports the written examinations held at Atlanta and Augusta, May 2-5, 1911. The number of subjects examined in was 10; total number of questions asked, 100; percentage required to pass, 80. At the examination held at Atlanta, the total number of candidates examined was 109, of whom 99 passed and 10 failed. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
Birmingham Medical College	(1909)	91
University of Alabama	(1910)	94
Atlanta College of Physicians and Surgeons	(1909) (1911)	85.5 80, 80, 80, 81.5, 82, 83, 83, 83, 83, 83, 83, 83.5, 83.5, 83.5, 84, 84, 84.5, 84.5, 84.5, 84.5, 85, 85, 85, 85.5, 86, 86, 86, 86, 86.5, 86.5, 86.5, 87, 87, 87, 88, 88, 89, 89, 89, 91, 92, 92.5.
Atlanta School of Medicine	(1911)	80, 80, 80, 80, 80, 81, 81, 81, 82, 82, 82.5, 83, 84.5, 85, 85, 85, 85, 85, 85, 85, 85, 85.5, 86, 86, 86, 86, 86, 86.5, 86.5, 86.5, 87, 87, 87, 87, 87.5, 88, 88, 89, 89.5, 91.
Kentucky School of Medicine	(1908)	83
Johns Hopkins University	(1907)	87.5, 95.5
Baltimore Medical College	(1905)	84.5
University of Maryland	(1910)	88.5
College of Physicians and Surgeons, Boston	(1910)	88.5
Barnes Medical College	(1900)	80
Medical College of South Carolina	(1906)	85
University of Nashville	(1911)	91
Meharry Medical College	(1911)	80, 81, 86
Chattanooga Medical College	(1905)	80
Non-graduate*		91
FAILED		
Hospital Medical College, Atlanta	(1911)**	
Atlanta School of Medicine	(1911)	76, 76, 77.5, 78.5
Atlanta College of Physicians and Surgeons	(1911)	78.5
Leonard School of Medicine	(1905)	71.5
Meharry Medical College	(1911)	78
Knoxville Medical College	(1908)	66.5
Non-graduate†		68.5

At the examination held at Augusta the total number of candidates examined was 27, of whom 23 passed and 4 failed. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
Medical College of Georgia	(1909) (1911)	83 81.5, 82, 83, 83.5, 83.5, 84.5, 84.5, 85, 85, 85.5, 85.5, 86.5, 87.5, 89, 89, 89.5, 90.5, 92, 92.5, 93.5, 94.
Harvard Medical School	(1878)	83.5
FAILED		
Medical College of Georgia	(1911)	75.5, 76, 76, 77

* This applicant will not obtain his license until he receives a diploma from the Atlanta School of Medicine in 1912, for which he has already qualified. He was admitted to the examination by special vote of the Board.

** Expelled from examination for cheating.

† This candidate's application indicated graduation from Meharry Medical College. Word from this school, however, states positively that he was not a graduate.

New Hampshire July Report

Mr. H. C. Morrison, regent of the New Hampshire State Board of Medical Examiners, reports the written examination held at Concord, July 6-7, 1911. The number of subjects examined in was 7; total number of questions asked, 70; percentage required to pass, 75. The total number of candidates examined was 15, of whom 13 passed and 2 failed. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
Medical School of Maine	(1910)	81
Baltimore Medical College	(1911)	81
Boston University	(1911)	84, 87

Harvard Medical School	(1902) (1911)	80 80
Dartmouth Medical School	(1910) (1911)	78 81, 83
University of Vermont	(1911)	76
FAILED		
Medical School of Maine	(1877)	64
Laval University, Canada	(1911)	71

New Mexico July Report

Dr. J. A. Massie, secretary of the New Mexico State Board of Health and Medical Examiners, reports that at the meeting held by that board, July 10-11, 1911, 23 candidates were licensed on presentation of satisfactory credentials. The following colleges were represented:

College	Year of Grad.
Denver and Gross College of Medicine	(2, 1909)
Northwestern University Medical School	(1904)
University of Louisville	(1911)
University of Louisiana	(1871)
Tulane University of Louisiana	(1892) (1909)
Baltimore University	(1897) (1903)
University of Maryland	(1909)
University Medical College, Kansas City	(1906)
Missouri Medical College	(1898)
St. Louis College of Physicians and Surgeons	(1897) (2, 1911)
Jefferson Medical College	(1898)
University of Pennsylvania	(1879) (1892) (1895)
Medico-Chirurgical College, Philadelphia	(1901)
Temple University	(1910)
University of Nashville	(1902)
University of the South	(1899)

South Dakota July Report

Dr. L. G. Hill, secretary of the South Dakota Board of Medical Examiners, reports the written examination held at Mitchell, July 12-13, 1911. The number of subjects examined

DISTRIBUTION OF GRAY AND WHITE MATTER: (1) in the bulb; (2) in the pons; (3) in the midbrain; (4) in the cerebrum; (5) in the cerebellum.

BLOOD-VESSELS: (a) To meninges; (b) to pia and brain substance. Circle of Willis and branches. Charcot's "artery of cerebral hemorrhage." Cerebral veins and sinuses.

PHYSIOLOGY OF THE BRAIN

SENSORI-MOTOR AREA: Fissure of Rolando, anterior and posterior central gyri, paracentral lobule, operculum, third frontal gyrus. Leg, arm and head regions. Hemiplegia, monospasm, Jacksonian epilepsy. Muscular sense, parietal lobes. Pressure, pain, temperature, sense.

SPEECH AREAS: Sylvian fissure, third frontal convolution, motor aphasia. First and second temporal convolutions, sensory aphasia. Visual speech area, lower parietal. Right- and left-handed persons.

SIGHT AREA: Occipital lobes, hemianopsia. Two visual centers.

SOUND AREA: First and second temporal convolutions.

PSYCHIC CENTERS: Frontal lobes. "Silent areas."

FUNCTIONS OF CEREBELLUM: Coordination, psychical functions, location of function.

FUNCTIONS OF MEDULLA: Respiratory and circulatory centers.

CEREBRAL TOPOGRAPHY: Fissure of Rolando, fissure of Sylvius, Horsley's method, Krönlein's method, Chiene's method.

REFERENCE BOOKS FOR THE SECOND MONTH

Keen's Surgery, vols. ii and iii.
Bryant and Buck: Surgery.
Ballance: Surgery of the Brain.
Horsley: Brain and Spinal Cord.
Krause: Surgery of the Brain.
Phelps: Injuries of the Brain and Its Membranes.
Starr: Brain Surgery.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

GEORGIA: Regular, Atlanta, October 10. Sec., Dr. C. T. Nolan, Marietta. Homeopathic, Atlanta, October 10. Sec., Dr. R. E. Hinman, 106½ Whitehall Street.

ILLINOIS: Coliseum Annex, Chicago, October 26-28 Sec., Dr. J. A. Egan, Springfield.

KANSAS: National Hotel, Topeka, October 10-12. Sec., Dr. H. A. Dykes, Lebanon.

LOUISIANA: New Orleans, October 19-21. Sec., Dr. A. B. Brown, 108 Baronne Street.

MICHIGAN: Legislative Bldg., Lansing, October 10-12. Sec., Dr B. D. Harison, 504 Washington Arcade, Detroit.

MISSISSIPPI: State Capitol, Jackson, October 10-11. Sec., Dr. S. H. McLean.

NEW JERSEY: The State Capitol, Trenton, October 17-18. Sec., Dr. H. G. Norton, 429 E. State Street.

NEW MEXICO: The Capitol, Santa Fe, October 9-10. Sec., Dr. J. A. Massie.

OKLAHOMA: Muskogee, October 10. Sec., Dr. John W. Duke, Guthrie.

WYOMING: Riverton, October 9-11. Sec., Dr. A. B. Tonkin.

Maryland June Report

Dr. J. McPherson Scott, secretary of the Maryland Board of Medical Examiners, reports the written examination held at Baltimore, June 20, 1911. The number of subjects examined in was 9; total number of questions asked, 90; percentage required to pass, 75. The total number of candidates examined was 152, of whom 130 passed and 22 failed. Sixteen candidates were licensed through reciprocity, 1 by special examination, and 1 under the exemption clause. The following colleges were represented:

* Reexamined.

The questions asked were as follows:

ANATOMY

1. Name varieties of cartilage. 2. Describe briefly two varieties named. 3. Describe the clavicle. 4. Describe the hip joint. 5. What arteries supply the heart with blood and where do they originate? 6. Give general description of testicles. 7. Describe the pericardium. 8. What are the parathyroid bodies? 9. Name the twelve pairs of cranial nerves. 10. Name principal muscles of the back.

PATHOLOGY

1. Mention a cause for each of the following conditions: edema of one leg, edema of both legs, edema of one arm, ascites, edema of the lungs, hydrothorax. 2. What is meant by the term compensation as used in heart diseases? By broken compensation? Trace the course of events depending on the latter condition. 3. Mention at least five diseases that are transmitted by insects. Name the carriers and the method by which the infection is introduced. 4. What is a cyst? Mention two forms of cyst that are commonly met with, and explain their causation. What is meant by the term encysted? 5. Describe briefly the gross and microscopic appearances of an atrophic cirrhotic liver. Mention the pathologic changes inherent to this condition. 6. Describe the formation of scar tissue and mention its principal characteristics. 7. What is the Widal reaction? 8. What is an aneurysm? Describe the formation of an aneurysm of the aorta. 9. How would you demonstrate the presence of bacteria in milk? How would you estimate the number in a cubic centimeter of milk? 10. What are the essential lesions of scarlet fever? What means would you use to prevent the spreading of the contagion in this disease?

CHEMISTRY

1. Explain the following terms: (a) Molecular weight, (b) precipitate, (c) valence, (d) oxidation, (e) efflorescence. 2. Give the general characteristics of acids. Define monobasic, dibasic and tribasic acid, and give an example of each. 3. Give the chemical names and composition of "calomel" and "corrosive sublimate." How may one be distinguished from the other? 4. Give one chemical antidote for each of the following: (a) Nitric acid, (b) oxalic acid, (c) arsenic trioxid, (d) morphine sulphate. 5. Give (a) one chemical test for albumin in urine, and (b) one test for sugar in urine. 6. What is the normal reaction to litmus paper of (a) blood, (b) saliva, (c) succus gastricus, (d) succus entericus, and (e) feces. 7. Give the chemical formula of each of the following: (a) Sulphuric acid, (b) hydrochloric acid, (c) potassium permanganate, (d) epsom salt, (e) ammonia water. 8. Define (a) amphoteric reaction, (b) calorie, (c) indicanuria, (d) hypoacidity, (e) hyperacidity. 9. Give the chemical formula and properties of hydrogen peroxid. 10. Complete the following equations: $Na_2CO_3 + HCl =$
$K + H_2O =$ $CO_2 + Ca(OH)_2 =$ $Mg + H_2SO_4 =$
$CuO + 2HNO_3 =$

PHYSIOLOGY

1. Name and locate the glands of the small intestines. 2. (a) Describe the normal pulse, its variations in infancy, youth and old age; (b) How does the pulse rate compare with respiration? 3. What is meant by blood-pressure and how estimated? (b) What are some

Medicolegal

Liability of Company for Medical Services Rendered to Injured Employee on President's Promise of Payment

(Scott vs. Monte Cristo Oil & Development Co. (Cal.), 115 Pac. R. 64)

The Court of Appeal, Second District, California, affirms a judgment in favor of a physician for professional services rendered and medicines furnished to an employee of the defendant company, who had been seriously injured, his skull being fractured, necessitating an operation of trephining. The plaintiff had been called by telephone and later told by the president of the company, in the presence of the superintendent, that the company would pay the bills; but the company contended that the evidence failed to show any authority, either express or implied, on the part of the president or superintendent of the corporation to act for it in making such agreement or incuring such liability.

No question of *ultra vires* or the corporation's having exceeded its charter powers, the court says, was involved. The superintendent received his orders and instructions on behalf of the corporation from its president, who instructed him to do all that he could for the boy. There was also evidence to the effect that the plaintiff, after dressing the employee's wounds at the bunkhouse, asked whether they would send him to the hospital as a county charge, or to the private sanatorium, where the hospital charges would be $25 per week.

If the injury to the employee was due to the negligence of the corporation, then, in the absence of contributory negligence on his part, the corporation would be liable to him for these claims and he might recover therefor. Such circumstances would constitute a sufficient consideration for the making of the agreement and raise a presumption that it was in the interest of the corporation to do what it could to reduce its liability for damages on account of such injury.

It could not be said that an agreement of this character, made under such conditions, would not be within the scope of authority vested in one charged with the general power shown to have been exercised by the president of the corporation. The directors did not meet in that county, all of its business there was transacted through its president, and, since he was held out by the corporation as possessing full power to act in its behalf in all matters arising and transacted in that vicinity, then, in the absence of anything to the contrary, the evidence was sufficient to raise a presumption that he was vested with the authority which he purported to exercise in making the agreement. Under the circumstances disclosed by the record, the court deems it but a reasonable inference to conclude that the making of this agreement by the president as such was within the scope of the powers vested in him by the corporation.

Moreover, conceding that the company was not responsible for the injuries received by the employee, and might have refused to assist or care for him in any way, nevertheless it recognized an obligation to do something toward relieving his suffering and assisting him, and did send him to the sanatorium and paid for the services rendered in such transportation, which, however small, constituted some ratification of the acts of its president.

The case was not unlike that of Fraser vs. San Francisco Bridge Company, 103 Cal. 79, where it was held under the circumstances of that case that the moral obligation resting on the defendant to furnish assistance and care to an injured employee, for which the corporation was in no wise responsible, constituted a sufficient consideration for the agreement made by the president of the company to pay a physician for professional services rendered such employee.

The finding in this case to the effect that the injury was received by the employee while performing the duties of his employment found no support in the evidence; but, under the court's view of the case, the error was not prejudicial and should be disregarded as immaterial.

Admissibility of Testimony in Case of Examination of Patient Through Interpreter

(Salminen vs. Ross (U. S.), 185 Fed. R. 997)

A United States Circuit Court, in Massachusetts, holds that in a personal injury case the testimony of a physician who examined the plaintiff through a companion who acted as an interpreter for the physician was not objectionable as mere hearsay, where, so far as the testimony of the physician included subjective symptoms and a history of the case communicated to him through the interpreter, that was merely testimony given by the physician as the reason for his conclusion, and the testimony was not admitted to prove the truth of the statement, but only to form the basis for an expert opinion. Whether the statements were derived directly from the patient or indirectly through an interpreter, they were insufficient to show the plaintiff's condition as a matter of fact.

Liability for Death Made Possible by Prior Surgical Operation

(Louisville & Nashville Railroad Co. vs. Chamblee (Ala.), 54 So. R. 681.)

The Supreme Court of Alabama, in affirming a judgment against the railroad company for damages for the death of a man from strangulation of the bowels, says that there was evidence tending to show that the handling of the man by the company's watchman caused the parting of the casing of the bowels at a place or places where previously a surgical operation had been performed. If the violent treatment alleged to have been received by the man had the effect to cause his death, or accelerate his dissolution as a consequence of the earlier surgical operation, the company, if shown otherwise to be liable, could not claim exemption from the result of its employee's (watchman's) acts in the course of his service to it.

Corrections in State Board Reports

Dr. G. M. Williamson, secretary of the North Dakota State Board of Medical Examiners, informs us that the graduate of the Keokuk Medical College, College of Physicians and Surgeons, 1906, examined July 5-7, 1911, received an average of 84.2 per cent. instead of 80 per cent. as was previously reported.

Correspondence from Dr. G. H. Sumner, secretary of the Iowa State Board of Medical Examiners, indicates that one of the candidates who failed at the examination held by that board, June 5-7, 1911, was a graduate of the Maryland Medical College, 1908, instead of the Baltimore Medical College as was previously reported.

The two reports referred to were published in The Journal, Sept. 16, 1911, on pages 1001 and 1002.

Book Notices

A System of Medicine. By Many Writers. Edited by Sir Clifford Allbutt, K.C.B., M.A., M.D., Regius Professor of Physic in the University of Cambridge and Humphry Davy Rolleston, M.A., M.D., F.R.C.P., Senior Physician, St. George's Hospital, Cambridge. Volume VIII, Diseases of the Brain and Mental Diseases. Pp. 1070, with illustrations. Volume IX. Diseases of the Skin With General Index. Pp. 869, with 170 illustrations. Cloth. Price, $6 net per volume. New York: Macmillan & Co., 1911.

In preparing the various volumes in this system, it has been the aim of the authors to publish one volume each year. In the main, this scheme has been carried out as planned, although on two occasions, two volumes have appeared in the same year. Volume I appeared in 1905 and the succeeding volumes have been published at intervals since, and were reviewed in The Journal. While this method of publishing may not appeal to some readers, it nevertheless possesses some advantages in that it is primarily historical. Each volume is complete up to the time of publication. It is not necessary at this time to mention the good features of the previous volumes of this work, but it may not be amiss to emphasize the value of the many references to current literature appended to each article. American works on medicine are woefully deficient in this respect.

Volume VIII, now before us, is devoted to the diseases of the brain and mental diseases. In the first edition the eighth volume also contained a discussion of the diseases of the skin, which are considered in Volume IX of the new edition. The most notable change in this portion of the work has been made in the chapter on meningitis, to which 66 pages are devoted. The author has not failed to include every known type, even that accompanying rheumatism and mumps. The same author contributes a very excellent article on acute polio-encephalitis, in which he subscribes to the current views held as to the etiology of the disease. Other new chapters are those on "Recurrent Paralysis," by J. Mitchell Clarke, and "Apraxia and Agnosia," by J. Collier. Naturally, many chapters have been revised or rewritten to keep pace with the great progress which has been made in neuriatry. Neither Freud nor psycho-analysis is mentioned. Mackenzie in his article on "Migraine" does not agree with Gould in his refraction error theory. He regards the disease as hereditary. A most commendable chapter is the one by Nicolson on "Criminal Lunacy." It bristles with valuable and instructive statistics and from every point of view is one of the best contributions on this subject. A short chapter on insanity and surgical operations by Dent presents this topic well.

Volume IX, the concluding volume, contains 750 pages on the "Diseases of the Skin" and the general index. The text is further elucidated by 170 illustrations and 2 plates, but unfortunately black-and-white pictures are of little value to depict skin lesions. Among the contributors to this volume are H. G. Adamson, H. R. Crocker, T. C. Fox, J. Galloway, J. Hutchinson, J. M. H. MacLeod and J. H. Sequeira. A very comprehensive chapter on the bacteriology of the skin introduces the subject of dermatology, which is presented clearly, fully and instructively. Each chapter is essentially a review of what is known to-day and the references cited at the end of each part are exceedingly valuable, giving the reader an opportunity to search further, if he so desires. Many chapters have been entirely rewritten, as for instance, the chapters on eczema, tumors, tuberculosis and pruritus. New ones have been added on such subjects as blastomycosis, sporotrichosis and calcareous deposits. On cursory examination, a most favorable impression is conveyed as to the scope and thoroughness of the work. Differences of opinion are not subject to review.

Tuberculosis Hospital and Sanatorium Construction. Written for the National Association for the Study and Prevention of Tuberculosis. By Thomas Spees Carrington, M.D., Assistant Secretary. Paper. Pp. 164. New York: 105 East 22d Street, 1911.

This book should be of assistance to those building sanatoriums, or to those adapting cottages for the use of the tuberculous. Excellent illustrations are given and detailed plans with measurements and descriptions, taking up various styles of architecture from simple to complex. Many of the well-known institutions of the country are here diagrammed.

Medicolegal

Liability of Company for Medical Services Rendered to Injured Employee on President's Promise of Payment

(Scott vs. Monte Cristo Oil & Development Co. (Cal.), 115 Pac. R. 64)

The Court of Appeal, Second District, California, affirms a judgment in favor of a physician for professional services rendered and medicines furnished to an employee of the defendant company, who had been seriously injured, his skull being fractured, necessitating an operation of trephining. The plaintiff had been called by telephone and later told by the president of the company, in the presence of the superintendent, that the company would pay the bills; but the company contended that the evidence failed to show any authority, either express or implied, on the part of the president or superintendent of the corporation to act for it in making such agreement or incuring such liability.

No question of *ultra vires* or the corporation's having exceeded its charter powers, the court says, was involved. The superintendent received his orders and instructions on behalf of the corporation from its president, who instructed him to do all that he could for the boy. There was also evidence to the effect that the plaintiff, after dressing the employee's wounds at the bunkhouse, asked whether they would send him to the hospital as a county charge, or to the private sanatorium, where the hospital charges would be $25 per week.

If the injury to the employee was due to the negligence of the corporation, then, in the absence of contributory negligence on his part, the corporation would be liable to him for these claims and he might recover therefor. Such circumstances would constitute a sufficient consideration for the making of the agreement and raise a presumption that it was in the interest of the corporation to do what it could to reduce its liability for damages on account of such injury.

It could not be said that an agreement of this character, made under such conditions, would not be within the scope of authority vested in one charged with the general power shown to have been exercised by the president of the corporation. The directors did not meet in that county, all of its business there was transacted through its president, and, since he was held out by the corporation as possessing full power to act in its behalf in all matters arising and transacted in that vicinity, then, in the absence of anything to the contrary, the evidence was sufficient to raise a presumption that he was vested with the authority which he purported to exercise in making the agreement. Under the circumstances disclosed by the record, the court deems it but a reasonable inference to conclude that the making of this agreement by the president as such was within the scope of the powers vested in him by the corporation.

Moreover, conceding that the company was not responsible for the injuries received by the employee, and might have refused to assist or care for him in any way, nevertheless it recognized an obligation to do something toward relieving his suffering and assisting him, and did send him to the sanatorium and paid for the services rendered in such transportation, which, however small, constituted some ratification of the acts of its president.

The case was not unlike that of Fraser vs. San Francisco Bridge Company, 103 Cal. 79, where it was held under the circumstances of that case that the moral obligation resting on the defendant to furnish assistance and care to an injured employee, for which the corporation was in no wise responsible, constituted a sufficient consideration for the agreement made by the president of the company to pay a physician for professional services rendered such employee.

The finding in this case to the effect that the injury was received by the employee while performing the duties of his employment found no support in the evidence; but, under the court's view of the case, the error was not prejudicial and should be disregarded as immaterial.

Admissibility of Testimony in Case of Examination of Patient Through Interpreter

(Salminen vs. Ross (U. S.), 185 Fed. R. 997)

A United States Circuit Court, in Massachusetts, holds that in a personal injury case the testimony of a physician who examined the plaintiff through a companion who acted as an interpreter for the physician was not objectionable as mere hearsay, where, so far as the testimony of the physician included subjective symptoms and a history of the case communicated to him through the interpreter, that was merely testimony given by the physician as the reason for his conclusion, and the testimony was not admitted to prove the truth of the statement, but only to form the basis for an expert opinion. Whether the statements were derived directly from the patient or indirectly through an interpreter, they were insufficient to show the plaintiff's condition as a matter of fact.

Liability for Death Made Possible by Prior Surgical Operation

(Louisville & Nashville Railroad Co. vs. Chamblee (Ala.), 54 So. R. 681.)

The Supreme Court of Alabama, in affirming a judgment against the railroad company for damages for the death of a man from strangulation of the bowels, says that there was evidence tending to show that the handling of the man by the company's watchman caused the parting of the casing of the bowels at a place or places where previously a surgical operation had been performed. If the violent treatment alleged to have been received by the man had the effect to cause his death, or accelerate his dissolution as a consequence of the earlier surgical operation, the company, if shown otherwise to be liable, could not claim exemption from the result of its employee's (watchman's) acts in the course of his service to it.

1. Abstracted in The Journal, June 17, 1911, p. 1849.

2. **Passing Leakage of Pulmonary Valve.**—Three cases are reported by Rudolf in which an evident mitral lesion so raised the pulmonary artery blood-pressure that that vessel and along with it the pulmonary orifice dilated and a murmur occurred, which came and went in two of them over a period of years. These three cases are examples of the so-called Graham Steell murmur. In two other cases cited no such cause seemed to exist, and probably the leakage was more due to relaxed tissues about the pulmonary orifice than to any marked increase in the blood-pressure of the pulmonary artery. A pulmonary systolic murmur, the commonest of all functional bruits, probably depends on a dilatation of the pulmonary artery, and in most cases tends to disappear. When, however, the dilatation involves the pul-

monary orifice so that a diastolic leakage occurs the condition is of more import, although even yet it may completely clear up. From the dilatable character of the pulmonary orifice, and on the other hand the resistant nature of the aortic one, Rudolf regards it as probable that most of the diastolic murmurs which come and go, and which are usually reported to be aortic in origin, are due to passing leakage at the pulmonary valve.

3. **Determining Blood-Pressure.**—Special attention was given by Goodman and Howell to sequence readings and to their interpretation, and it is to this aspect alone that the present paper is dedicated. They interpret variations in sequence readings by assuming that each phase has a physiologic factor in its production in addition to the anatomic unit, and though these hypotheses have not the firm basis of an experimental control, yet clinical experience has lent some weight to their probable correctness. The first phase, or tone phase, serves principally as an index as to how far the pressure must fall before the blood-current can be sustained past the obstruction in the vessel caused by the cuff, at a sufficient velocity and for a sufficient duration to produce the murmur. Hence the information it affords is of negative rather than of positive value. In other words, its normal duration is of no value, but an increase or decrease in length is of importance. The second, or the murmur phase, seems to be especially dependent on cardiac effectiveness, for it is in this phase alone that the individual sounds possess a distinct element of duration, and this protracted energy, for so it must be regarded, must evidently come from the heart. The third phase, or second tone phase, depends not alone on cardiac efficiency, but also on the character of the vessel wall. The more sclerotic the vessel and the greater the cardiac hypertrophy, the more favorable are the conditions for the production of a clear tone. As the fourth phase, or dull tone, may be produced by a resilient vessel receiving a normal pulse shock, or by a rigid vessel receiving a weakened shock, its interpretation is more difficult, but its study quite as interesting.

If these assumptions are correct, it is quite evident that increases in the second and third phases are dependent on cardiac strength and circulatory efficiency, while the first and the fourth phases suffer increase when there is cardiac weakness. Furthermore, in dealing with increases or decreases in any particular phase, it is important to know at the expense of what adjacent phase this has occurred. It is apparent that an increase in the third phase, for example, at the expense of the second, has not the same significance as an increase of this phase at the expense of the fourth. In the first instance the unit of cardiac strength, obtained by adding the lengths of the second and third phases, has not been materially changed, while in the latter it has been increased. For this reason the authors recommend that the sum of the second and third phases be compared with the sum of the first and fourth phases, in order to determine whether the elements of force or those of weakness are predominating.

4. **Sclerosis of Superficial Veins.**—The chief features presented by Brooks' case were, a diffuse, isolated sclerosis of the superficial veins of the inner side of the thigh with phlebitis and thrombosis of one. This condition is remarkable in that the sclerosis was apparently limited to the superficial veins, and was relatively much more marked in them than in the other veins or arteries. Although the coagulation time of the blood was considerably reduced the chief factor back of it was the markedly altered, and in this instance clearly sclerotic alteration in the walls of the veins. With no other evidence at hand, and the case was most carefully studied in all its aspects, Brooks believes that this selective venous sclerosis was induced by syphilitic infection either congenital or early contracted.

7. **Functional Renal Sufficiency.**—Quantitative colorimetric determinations of indigocarmin and phenolsulphonephthalein Thomas believes are of very great value in the estimation of the total renal function, particularly in such conditions as nephritis and damaged kidneys, incident to prostatic enlargement, etc., causing poor drainage and resulting in vis a tergo pressure. These substances routinely employed by the surgeon as indicators for or against surgical intervention, particularly in contemplated prostatectomies, but likewise in other fields of surgery, will aid materially in the reduction of operative mortality. Although, he says, each substance has its particular advantages and indications as a test, indigocarmin, at least for the purposes of the surgeon, especially in the diagnosis and prognosis of unilateral renal disease, seems just as useful and possibly more practical than the new drug phenolsulphonephthalein. Phenolsulphonephthalein in many respects is an ideal substance for employment in studying the pathology and physiology of the kidney. It may possibly be more sensitive than indigocarmin, in fact, may prove to be too delicate. On the other hand, the technic of the test is extremely simple and may be employed painlessly. Preference should be extended to this drug over indigocarmin whenever it is desirable to learn the total or combined efficiency of both kidneys.

8. **Actinomycosis in Norway.**—The authors' series includes 87 cases, and the lesions were distributed as follows: 45 per cent. of the cases occurred on the neck and face (all cured); 23 per cent. in the thorax (all dead); 30 per cent. in the abdomen (19 dead, 5 cured); 3 per cent. on the skin (1 dead, 1 cured). Fifty-six cases occurred in men, 27 in women, and in 7 the sex was not given. Two occurred in the first decade (boys); 12 occurred in the second decade (10 men, 2 women); 26 occurred in the third decade (17 men, 9 women); 16 occurred in the fourth decade (10 men, 6 women); 13 occurred in the fifth decade (8 men, 5 women); 7 occurred in the sixth decade (4 men, 3 women); 3 occurred in the eighth decade (3 men). Among the 39 cervico-facial cases, in 15 the lesions were located on the cheek, especially on the maxilla, the forehead and the parotid region; in 20 they were on the mandibular or on the submental region and in 3 they were located farther down the neck, and 1 tumor was on the tongue. The infection atrium was in every instance the mucous membrane of the oral cavity, and often the part covering the gums. There was no evidence of the fungi having entered by carious teeth. All the 39 patients recovered.

In the thoracic group the primary lesion was always in the lungs, and, as a rule, in the lower lobes. The disease simulated an atypical bronchopneumonia or pulmonary tuberculosis, with fever, dyspnea, cough and a rusty, tenacious sputum, which, as a rule, contained the characteristic sulphur granules. Everyone of these cases terminated fatally. The average duration was one to one and one-half years. One patient lived on for eight years. The primary lesion of the abdominal cases was some part of the alimentary tract, most often the vermiform appendix. There were no primary lesions in the rectum, bladder or genital organs, although gravitation abscesses did extend into these organs. The disease occurred as localized abscesses most often in the ileo-cecal region. These spread both extra- and intra-peritoneally. Liver abscesses were frequently found. The average duration of the fatal cases was one to two years. In the 2 patients where the disease was primary in the skin, 1 had a localized abscess on the arm which soon healed. The other had a phlegmonous infection of the leg, that originated from an ulcer that started during the harvest. This man's leg was amputated, but he died.

9. **Embryos of Trichinella Spiralis in Blood.**—The examination of the blood sediment for the embryos of *Trichinella spiralis* suggesting trichiniasis. The earliest time at which the Lamb believes to be a valuable means of diagnosis in cases embryos may be found in the blood is on the sixth or seventh day after infection. The latest date is not so accurately fixed. While the parasites have not been found later than the twenty-seventh day after infection in guinea-pigs, or later than the twenty-second day after the onset of symptoms in man, there is some ground for the belief that they may occasionally be recovered in the fifth or possibly the sixth week after injection. Lamb has found this method of greatest value in those cases where the diagnosis is doubtful and especially where the patient refuses permission to excise a piece of muscle or where the muscle findings are negative.

CURRENT MEDICAL LITERATURE

10. **Septic Rhinitis of Scarlet Fever.**—Kolmer and Weston regard the nasal discharges as of primary importance in the etiology of the return case of scarlet fever, because the true rhinitis of scarlet fever is septic in character, distinctly infectious in itself, and probably harbors the contagium of scarlet fever. They found the bacterin treatment of cases of septic rhinitis to be more satisfactory than the usual treatment. It shortens materially the time required for cure and decidedly aids in decreasing the number of return cases.

11. **Chronic Pneumonia.**—A very exhaustive study of ten cases of chronic pneumonia leads Milne to conclude, (1) that they are a possible sequence of acute pneumonia; (2) that they are particularly found in subjects debilitated by some intercurrent condition, but that no single factor such as cardiac conditions, nephritis, arteriosclerosis, alcoholism, tuberculosis or syphilis is responsible for its production. The onset is extremely irregular in type, and may be acutely febrile, simulating the usual commencement of a croupous pneumonia in subjects of the same age or typical signs of pneumonic consolidation may be evident without there having been any especial initial pneumonic symptoms or there may even be no increase in temperature or abnormality of the pulse and respiration rates. The prognosis in such conditions is bad, as not only is death very frequent from cardiac insufficiency, but complications, such as empyema, pericarditis, peritonitis, meningitis, etc., are extremely frequent, and what is very important that any of these conditions may supervene even after long periods of apparent quiescence of the pneumonia—seven out of the ten cases were complicated in this way, an infinitely higher proportion than occurred in the rest of the pneumonia series; forty-one out of ninety-five cases of lobar pneumonia, including nine which had become organized, and ten out of sixty-four cases of bronchopneumonia, including one which was organized, were complicated. Such conditions, Milne believes, may undoubtedly be recovered from as far as symptoms are concerned, yet maintaining physical signs of pneumonic consolidation. It is just such cases which are apt to be mistaken for tuberculosis or possibly syphilitic fibrosis. In this connection it is also possible that the development of bronchiectasis or subsequent tuberculous infection may further complicate the case. Collapse, tubercle, infarction and syphilis of the lung, etc., are distinguishable from chronic pneumonia. Once organization processes in the lung have advanced to any marked extent one cannot imagine any complete restoration, as some cicatrization must be permanent.

27 *Stab Wound of Heart, Drainage of Pericardium, Recovery. H. S. Lott, Winston-Salem, N. C.

27. **Stab Wound of Heart.**—In the case cited by Lott the wound was found to be about midway on a line drawn just a little upward from the left nipple to the sternum. A free incision was made, exposing the fourth costal cartilage, which had been cut through transversely, the knife having entered the structures beyond, and in such direction as to indicate some injury to the heart. On the removal of this cartilage in two sections and the introduction of the fingers into the wound, blood-clots were found, as also a ragged puncture through pleura, lung structure, pericardium and into the heart muscle, for a depth quite sufficient to be easily perceptible to the touch, although not penetrating into its cavity, and situated at a point in the upper third of the ventricle quite near to the line of division between this and the auricular cavity. The wound in the muscular wall of the heart was not of such depth as to justify closure with stitches; nor did Lott feel inclined to close the pericardium and other supervening structures, thus making a sealed wound. But considering the infected weapon, the deep puncture and the unavoidable trauma from blood-clots and manipulation, he determined to drain both pericardial and pleural cavities. In order to accomplish this, two pieces of rubber tubing were used, each one of them split open on one side for its entire length, and its lumen filled with a soft gauze wick. One of these tubes, the longer one, was passed through the rent in the pericardium and well down to the limit of the apex of the heart; and the other one, not quite so long, through the rent in the pleura and lung tissue and well down into the pleural cavity, posteriorly. These were fixed in the usual manner with safety pins, and an ample gauze and cotton dressing made secure with a many-tailed bandage. Hypodermics of morphia were given to relieve pain and secure quiet, and during this first forty-eight hours the clinical picture was a most interesting one. The heart was very erratic, the pulse going all gaits, ranging from 100 to 140. After forty-eight hours the tubes were drawn up for about 1 inch and cut off, and this was continued each day until they were out of the cavities. Drainage during this time was very free. The dressings were not disturbed. This drainage lessened each day, and by the time that the tube was withdrawn from the pericardial cavity, had practically ceased, and from that source there was no further trouble. The heart's action became more regular, but its rate was accelerated, ranging throughout this time from 100 to 112; and finally, when he left the hospital about five weeks from the time of his entrance, the range of the pulse was from 80 to 90 in the twenty-four hours.

31 *Dermatitis Vegetans in Infants. G. W. Wende and H. K. De Groat, Buffalo
32 Differential Study of Multiple Benign Cystic Epithelioma and Adenoma Sebaceum in the Negro. R. L Sutton, Kansas City

31. **Dermatitis Vegetans in Infants.**—The authors emphasize the occurrence in infancy of a clinically well-defined and charactersitic group of cases of dermatitis vegetans. They report four cases and review six others. All occurred in healthy infants under 1 year of age. Six developed in the course of eczema and four independently of any other dermatosis. In six patients the lesions were limited to the face with the exception of a few scattered lesions on the scalp; in the other four, the wrists, arms and legs were involved. The initial lesion was a papulo-pustule. The pustule soon dried up or ruptured and discharged its contents, and on the reddened base there developed the characteristic secondary lesion of the disease. This consisted of vegetating masses varying from split-pea to walnut size or larger, and elevated from ¼ to 1 inch above the skin surface. Some of the lesions developed from the base of a single pustule, others by the coalescence of several. The individual lesions often contained miliary pustules, especially near their borders, exuded a purulent fluid on pressure, and when the crusts or scales covering them were removed presented a warty appearance. There was no constitutional reaction and disturbance of sensation was apparently very slight. A gratifying feature was the benign course of the disease, all cases yielding to antiseptic treatment in from two to eight weeks.

36. **Etiology of Pellagra.**—Thorington suggests the mosquito as a probable factor in the conveyance of pellagra and points to the similarity in symptoms between pellagra and malaria.

39. **Lingual Tonsil.**—Dupuy emphasizes that there is such a structure as the lingual tonsil, which, while a diminutive lymphoid deposit, is quite frequently the source of considerable distress, and that proper remedial measures afford the most gratifying relief. The enlargement of the lingual tonsil is seldom of sufficient dimensions to make it feasible for excision, and the profuse, and perhaps dangerous, bleeding renders it inadvisable to resort to a cutting operation as a routine measure. The galvano-cautery, properly applied, will reduce the ordinary hypertrophies, and is equally effective in destroying the lingual varix. In the acute and subacute inflammations, the silver salts, iodized phenol and menthol, in spray form, are of undoubted efficiency.

45. **Aseptic Hospital Floor.**—Fox says that, perhaps, hospital architects have not attached enough importance to the subject of hospital floors. In spite of the present-day system of ventilation, the isolation of kitchens, laundries and closets, the removal of all dirt of every character, the frequent use of disinfectants and the sterilizing of all instruments, the hospital cannot be sanitary unless it is provided with an aseptic floor. The wooden floor so common in many of our finest hospitals is not only quite out of keeping with the sanitary arrangements of the rest of the building, but it is a positive danger, from the fact that it becomes a harbor for microorganisms and infectious growths of all kinds. Wood, terrazzo, lead, tile, marble, glass, rubber and monolithic materials have been used, but none of these has proven entirely satisfactory. After examining all of the proposed floor materials, it must be admitted that the best so far discovered is the floor of baked clay tile, which consists principally of silicate of alumina, and is an inorganic substance which attains a greater hardness than almost any natural stone. It is so hard that a sharp steel point cannot scratch it, but merely makes a mark on it like a lead pencil. As a silicate of aluminum, it cannot be attacked by any acid, with the exception of hydrofluoric, which there is no occasion to use. As vegetable growths require nothing in the way of clay for their development, the clay is absolutely sterile as far as they are concerned. There has been much said about the cracks, or joints between the tile, but these are completely filled with pure cement grouted in hard so that the joint is but a joint in appearance and not in the sense of the open or unfilled joints of the wooden or rubber tile floor. Baked clay tiles, even in the joints between them, are nonabsorbent, germ-proof, fire-proof, impossible to stain, easy to keep clean, pleasing to the eye and very durable. While the "perfect hospital floor" may still be a thing of the future, the nearest approach to this goal of perfection has been reached by the clay tile, the sanitary and durable qualities of which are as yet unsurpassed by any flooring material.

50. **Von Recklinghausen's Disease.**—In four cases of von Recklinghausen's disease, occurring at the Lakeside Hospital in the past ten years, three patients had multiple cutaneous tumors and pigmentations; while in three of them large Ranken-neuromata, two of the face and one of the back, were found. In one patient an immense neuroma lymphangiectatica of the sternum was present. No especial functional disturbances were noted except pain in the cutaneous nodules in one of the cases and severe frontal headaches in another. In two of the cases the tumors were congenital, in another the growths were present for years; while in another trauma at the age of 2 years was given as the cause of the growth. Heredity was present in but one case, the patient's mother and three sisters being affected to his knowledge. Recurrence of a Ranken-neurom of the face, following operation was found in one case, but there was no sarcomatous change as is found in 12 per cent. of such cases. In three of the cases histologic examination revealed fibromata with enclosed nerves; while in the other patient the tumors were cut from nerves at the time of examination, though nothing was said of nerve tissue in the histologic description of the sections. It was impossible to corroborate Verocay's findings that the tumors arise from the sheath of Schwann or its precursor neurons and therefore should be called neurinoma. However, in one case the nerves were not well defined from the surrounding fibrous tissue and there was a marked increase in the nuclei of the sheath of Schwann.

63 and Suggestions for Its Betterment.
64 Progress of Medical Research in Philippine Islands. W. E. Musgrave.

61. **Urinary Pigment as Diagnostic Sign in Malaria.**—The urine from fifteen cases of malaria was examined by Bowman following the technic described by Uriolla for finding pigment elements and in fourteen of these specimens pigment granules were *found*. Then twenty-four specimens from cases with no symptoms of malaria and no previous history of "chills and fever" were examined and in twenty of these pigment granules were found similar to those seen in urine from the malaria cases. Bowman says that although pigment may be present in the urine in cases of malaria, as a method of diagnosing the disease it would seem to require a great deal of experience to distinguish the different kinds of pigment, definitely enough to make the examination of any practical value.

62. **Rupture of Uterus.**—Obstetric curettages (not gynecologic) are held to be very dangerous by Calderon and, he

says, should be done by the fingers whenever possible. In transverse presentations of dead or moribund fetuses, with the os dilated, the membranes broken, and the uterus in a state of tetanic contraction Calderon would not do a podalic version. Embryotomy should be performed to save the life of the mother. In cases with rigid, undilatable os where a rapid evacuation is necessary, as in cases of eclampsia and placenta prævia, Calderon says, it is better to extract the fetus by the abdominal route, otherwise the mother is exposed to the danger of cervical uterine tears.

67. **Extirpation of Tumors of Vomer Through Roof of Mouth.**—In two cases of malignant disease of the vomer, each with a pear-shaped enlargement of the septum which completely closed the posterior nares, Mayo was able to remove the growth through the roof of the mouth by the removal of a section of the bone 1 inch long and ¾ of an inch wide. In neither of these cases was it necessary to sever the soft palate as advised by Nélaton—a procedure which, he says, complicates the technic of the operation and the after-care of the patient.

82. **Metabolism of Mucic Acid.**—Rose found that mucic acid, in doses of 10 to 20 grams, was not completely oxidized by rabbits, but was in part excreted unchanged in the urine. When given in doses of 20 grams to a medium-sized dog, mucic acid was excreted unchanged in the urine in amounts large enough to identify. The greater portion of the acid was not recovered. After large doses of mucic acid, only a very small increase in oxalic acid elimination occurs in rabbits and dogs. This increase is by no means as large as would be expected if mucic acid were one of the precursors of oxalic acid. Rabbits and dogs receiving the amounts of gallactose and lactose stoichiometrically equivalent to 20 grams of mucic acid, excrete no mucic acid in the urine. Obviously, therefore, mucic acid is not an intermediary product in the metabolism of galactose-yielding sugars.

87. **Commercial Ice Cream.**—The bacteriologic examination of ice cream in the city of Boston made by the authors showed that much of it contains more than 500,000 bacteria per cubic centimeter, the legal maximum. This is due partly to the large bacterial flora of the cream used, to long storage of the product, and in some cases to unsanitary methods of manufacture. Their analysis of samples of cream indicate that even the careful manufacturer, unless he has an exceptionally good cream-supply or depends on pasteurization, cannot expect to produce ice cream with a bacterial content within the legal limit.

103. ***Exophthalmic Goiter.***—The thyroids of sixty-nine cases were studied by Marine and Lenhart. They found that the anatomic changes in the several body tissues in exophthalmic goiter are variable and manifold. The most prominent and most constant change is active hyperplasia of the thyroid and lymphoid tissues. These changes are not constant, since the exophthalmic goiter syndrome, as at present recognized, may coexist with a normal thyroid, with a colloid goiter, with an actively hyperplastic thyroid, with an atrophic thyroid or with a tumor of the thyroid. The great majority of individuals presenting this syndrome in recognizable form have some degree of thyroid and lymphoid hyperplasia, and

all true cases have had, during the developmental stage, active thyroid and lymphoid hyperplasia. Active thyroid and lymphoid hyperplasia are not specific for this syndrome, since similar anatomic changes are present in a variety of other abnormal body states.

The series of anatomic changes which occur in a thyroid as it passes from its normal or its colloid state through active hyperplasia and on to atrophy or to colloid goiter represents this tissue's biologic reaction whenever those biochemical disturbances in the organism's nutrition occur which excite its compensatory activity. Active thyroid hyperplasia means thyroid insufficiency, and although the causes which excite this activity are unknown and, therefore, may or may not be multiple, still, the basic anatomic reaction of the thyroid tissue seems to be the same in all the several clinical varieties of goiter and, indeed, seems to be the only one with which the thyroid tissue is endowed. The only defined physiologic activity of the thyroid secretion is that determined by its iodin content. Iodin is related to the exophthalmic goiter thyroid in the same way that iodin is related to the thyroid of other clinical associations and of other animals as well, viz., that iodin varies inversely with the degree of active hyperplasia. The ability of the exophthalmic goiter thyroid to take up iodin varies with the degree of active hyperplasia (hence inversely with the amount of iodin present) and is similar to that of other active thyroid hyperplasias in man and the lower animals. Iodin induces the same series of anatomic changes in exophthalmic thyroid goiter as in the other varieties of thyroid hyperplasias in man and animals.

The temperature and pulse reactions both before and after operation tend to vary with the degree of thyroid and lymphoid hyperplasia. The differences between the reactions in cases with normal or with colloid glands and the reactions in cases with marked hyperplasias are too slight for a suggestion of any cause and effect relation. The pulse and temperature reactions and the thyroid hyperplasia are parallel and resultant phenomena dependent on more general and more remote causes. An incomplete exophthalmic goiter syndrome may exist with the thyroid normal, or, the thyroid may be markedly hyperplastic with the syndrome absent, or, finally, the histologic structure and iodin content of the thyroid in a given case of exophthalmic goiter may be reversed without necessarily modifying the symptom-complex. Myxedema does not precede; it occasionally accompanies, but usually supervenes late in the course of exophthalmic goiter and is to be looked on as the end stage of thyroid insufficiency. The immediate postoperative mortality with its associated high temperature and pulse-rate in uncomplicated cases, varies with the degree of active lymphoid and thyroid hyperplasias and is most probably the result of the organism's profound general weakness and exhaustion. The degree of active lymphoid and thyroid hyperplasia is therefore the best index of the severity of the disease. The authors emphasize that the essential physiologic disturbance of the thyroid in exophthalmic goiter is insufficiency, its reaction compensatory and its significance symptomatic.

107. **Water-Drinking.**—The problem studied by Hawk was the activity of the pancreatic function under the influence of water-drinking at meal time. Normal men were used as subjects and were required to ingest a diet uniform in all respects from day to day. Three experiments were made, each experiment being divided into three periods; a fore period in which the subject was brought into nitrogen equilibrium through the ingestion of the uniform diet supplemented by a minimal water ingestion; a water period during which the water ingestion at meal time was increased from 1,500 to 4,000 c.c. per day; and an after period in which the dietary conditions of the fore period prevailed. Two of the experiments were on the influence of moderate water-drinking and in these the volume of the extra water ingested during water period was 1,500 c.c. per day or 500 c.c. per meal. In the third experiment the influence of copious water-drinking was studied and in this instance the subject was required to ingest on each day of the water period 4,000 c.c. above that ingested in the fore and after periods. On the basis of the data gathered in this and in associated investigations Hawk is prepared to draw the general conclusion that the ingestion of quantities of water at meal-time ranging in volume from ½ to 1⅓ liters stimulate the pancreatic function in two ways: first, a direct stimulation of the nervous mechanism of the pancreas brought about while the water is still in the stomach and, second, an indirect stimulation brought about on the entrance of the increased volume of acid chyme into the duodenum. The drinking of water with meals ought therefore to bring about a more rapid and complete digestion and absorption of the fat and carbohydrate constituents of the diet, two observations verified by experimentation in the laboratory.

125. **Experimental Poliomyelitis.**—On the basis that the virus of anterior poliomyelitis lurks in the dust and that the nasopharynx must be the point of entry, the authors collected the dust of rooms wherein cases of poliomyelitis occurred and prepared extracts from these sweepings, which they injected into monkeys (of the species Rhesus) subcutaneously, intraspinally and intracerebrally. Until now they have used six monkeys for their experiments. The sweepings were obtained from cases of from six months' to three days' duration after the onset of the paralysis. The following is a report of one of these experiments: August 29, they obtained the sweepings of a room wherein a 4-year-old child was stricken with poliomyelitis and was then two days paralyzed. In this room the child passed most of its time and also was there confined to bed. The dust, about 50

CURRENT MEDICAL LITERATURE

grams, was macerated overnight with 30 cubic centimeters of sterile water and then shaken for one hour. The mixture was filtered through a paper filter and 15 cubic centimeters of this filtrate were passed through a special Bougé filter under high pressure within an hour.

Within eighteen hours after the collection of this dust 5 cubic centimeters of the filtrate were injected into a monkey through the spinal canal after having first withdrawn 5 cubic centimeters of a clear spinal fluid and 8 cubic centimeters were injected subcutaneously. After the injection the animal was depressed and sullen and inattentive to its surroundings. On the following day the monkey was perfectly well and remained so until September 4, six days after the injection, when it was very ill and paralyzed. The animal presented the following symptoms: Flaccid paralysis in the right foreleg, which was hanging down from his side; he was unable to move it. There was a marked paresis of both hind legs, most pronounced in the left. He was able only with great difficulty to move about in his cage and this he accomplished by holding on to the bars with the left foreleg and hopping about. The patellar and plantar reflexes were absent. On extending the hind legs he shrieked, evidently from pain. He was chewing his food at times, but was rather sullen and depressed, keeping continually to a corner of his cage, holding on with his left forepaw, and lying down when unobserved. The muscles of his neck were not rigid, the pupils were normal and reacted to light promptly. A lumbar puncture was made repeatedly, but without success. Two drops of a gelatinous material were obtained from the needle, after withdrawing it from the spinal canal.

September 6, two days later, he still showed all the symptoms mentioned, but more marked, and still chewed his carrot. A spinal puncture was made and 2 drops of a gelatinous material obtained.

The animal was then killed and the following are the results of the autopsy: There was a marked hyperemia of the meninges in the lumbar region and a lesser one in the cervical region; the vessels of the brain cortex and cord were markedly congested. This hyperemia was evident at all the levels of the cord, in the medulla, the pons, the ventricles and basal ganglia. The cord and brain presented an edematous condition. On section, one could note hemorrhages in the gray substance of the cord, especially in the lumbar and cervical regions. There were also some hemorrhagic foci in the medulla, while the white and gray substance of the brain presented microscopically a normal appearance. The viscera presented the following changes: Areas of congestion in the middle and lower lobes of the left lung; the spleen was firm and congested, but not enlarged; the omentum was adherent to the cecum and all the visceral vessels were very much congested. All other organs and glands were, to all appearance, normal.

Sections of the spinal cord, cerebellum, pons, medulla, brain, spinal and basal ganglia were now emulsified in 50 cubic centimeters of normal salt solution and preserved for injections. The authors believe that they have thus proved that: Acute poliomyelitis is both infectious and contagious; that it is propagated by the dust, and that the nasopharynx must be the port of entry.

1. **Keratomalacia.**—Keratomalacia is essentially a disease of early infancy. The average age of Stephenson's thirty-one cases was four and one-half months. He has never seen the disease except in the children of the poor. The disease hardly ever occurs in breast-fed babies. Two alone of Stephenson's patients, or 6.46 per cent., were entirely breast fed. Syphilis was diagnosed clinically in seven, or in 22.58 per cent. Tuberculosis is an important cause of keratomalacia in infants. It existed in six, or 19.36 per cent. of the cases, the diagnosis being made during life in three and after death in three of the children. Of the twelve fatal cases tuberculosis was present in three. The disease was of the generalized type, as is usual in children so young with pulmonary or meningeal manifestations. Marasmus, pure and simple, accounted for seven, or 22.58 per cent. of the thirty-one cases. In two of the cases, or 6.45 per cent., the cause of the corneal mischief remained altogether obscure.

2. **Acute Abdominal Disease in Childhood.**—Clogg's own experience of ninety-eight cases of the "acute abdomen" in children under 12 years of age shows the diseases represented as follows: Appendicitis, fifty-four cases, pneumococcal peritonitis, six cases, inflammation of the diverticulum of Meckel, two cases, intussusception, twenty-eight cases, intestinal obstruction by a band, three cases, intestinal obstruction from adhesions, four cases, intestinal obstruction from pressure of mesenteric glands, one case. No case of gastric or duodenal ulcer came under his observation.

11. **Mayor's Scarf.**—Mayor's scarf consists of a square of stout material measuring 40 inches across, folded obliquely; 40 inches of an ordinary 3-inch bandage; a plug of carded cotton about 6 inches long and 3 or 4 inches thick; a dozen stout safety-pins. Place the plug of cotton in the arm-pit, bring the bent elbow close to the trunk and apply the base of the triangle formed by the scarf above the elbow, the apex being below. Draw it tight round the trunk and fix the ends of the scarf firmly at the back with safety-pins. The middle of the base of the triangle must not be opposite the arm, but nearer the middle line of the body, and the edge of the

all true cases have had, during the developmental stage, active thyroid and lymphoid hyperplasia. Active thyroid and lymphoid hyperplasia are not specific for this syndrome, since similar anatomic changes are present in a variety of other abnormal body states.

The series of anatomic changes which occur in a thyroid as it passes from its normal or its colloid state through active hyperplasia and on to atrophy or to colloid goitèr represents this tissue's biologic reaction whenever those biochemical disturbances in the organism's nutrition occur which excite its compensatory activity. Active thyroid hyperplasia means thyroid insufficiency, and although the causes which excite this activity are unknown and, therefore, may or may not be multiple, still, the basic anatomic reaction of the thyroid tissue seems to be the same in all the several clinical varieties of goiter and, indeed, seems to be the only one with which the thyroid tissue is endowed. The only defined physiologic activity of the thyroid secretion is that determined by its iodin content. Iodin is related to the exophthalmic goiter thyroid in the same way that iodin is related to the thyroid of other clinical associations and of other animals as well, viz., that iodin varies inversely with the degree of active hyperplasia. The ability of the exophthalmic goiter thyroid to take up iodin varies with the degree of active hyperplasia (hence inversely with the amount of iodin present) and is similar to that of other active thyroid hyperplasias in man and the lower animals. Iodin induces the same series of anatomic changes in exophthalmic thyroid goiter as in the other varieties of thyroid hyperplasias in man and animals.

The temperature and pulse reactions both before and after operation tend to vary with the degree of thyroid and lymphoid hyperplasia. The differences between the reactions in cases with normal or with colloid glands and the reactions in cases with marked hyperplasias are too slight for a suggestion of any cause and effect relation. The pulse and temperature reactions and the thyroid hyperplasia are parallel and resultant phenomena dependent on more general and more remote causes. An incomplete exophthalmic goiter syndrome may exist with the thyroid normal, or, the thyroid may be markedly hyperplastic with the syndrome absent, or, finally, the histologic structure and iodin content of the thyroid in a given case of exophthalmic goiter may be reversed without necessarily modifying the symptom-complex. Myxedema does not precede; it occasionally accompanies, but usually supervenes late in the course of exophthalmic goiter and is to be looked on as the end stage of thyroid insufficiency. The immediate postoperative mortality with its associated high temperature and pulse-rate in uncomplicated cases, varies with the degree of active lymphoid and thyroid hyperplasias and is most probably the result of the organism's profound general weakness and exhaustion. The degree of active lymphoid and thyroid hyperplasia is therefore the best index of the severity of the disease. The authors emphasize that the essential physiologic disturbance of the thyroid in exophthalmic goiter is insufficiency, its reaction compensatory and its significance symptomatic.

107. **Water-Drinking.**—The problem studied by Hawk was the activity of the pancreatic function under the influence of water-drinking at meal time. Normal men were used as subjects and were required to ingest a diet uniform in all respects from day to day. Three experiments were made, each experiment being divided into three periods; a fore period in which the subject was brought into nitrogen equilibrium through the ingestion of the uniform diet supplemented by a minimal water ingestion; a water period during which the water ingestion at meal time was increased from 1,500 to 4,000 c.c. per day; and an after period in which the dietary conditions of the fore period prevailed. Two of the experiments were on the influence of moderate water-drinking and in these the volume of the extra water ingested during water period was 1,500 c.c. per day or 500 c.c. per meal. In the third experiment the influence of copious water-drinking was studied and in this instance the subject was required to ingest on each day of the water period 4,000 c.c. above that ingested in the fore and after periods. On the basis of the data gathered in this and in associated investigations Hawk is prepared to draw the general conclusion that the ingestion of quantities of water at meal-time ranging in volume from ½ to 1⅓ liters stimulate the pancreatic function in two ways: first, a direct stimulation of the nervous mechanism of the pancreas brought about while the water is still in the stomach and, second, an indirect stimulation brought about on the entrance of the increased volume of acid chyme into the duodenum. The drinking of water with meals ought therefore to bring about a more rapid and complete digestion and absorption of the fat and carbohydrate constituents of the diet, two observations verified by experimentation in the laboratory.

117. **Radium Treatment in Cancer of Digestive Tract.**—Einhorn believes that benefit is obtained in inoperable cancer of the stomach from the application of radium directly by an apparatus introduced into the stomach by way of the esophagus. By this means, he says pain is diminished, hemorrhage is controlled, and life is prolonged, and if the treatment is begun early enough absolute cure may be obtained. The author presents the histories of seven cases of disease of different parts of the stomach.

125. **Experimental Poliomyelitis.**—On the basis that the virus of anterior poliomyelitis lurks in the dust and that the nasopharynx must be the point of entry, the authors collected the dust of rooms wherein cases of poliomyelitis occurred and prepared extracts from these sweepings, which they injected into monkeys (of the species Rhesus) subcutaneously, intraspinally and intracerebrally. Until now they have used six monkeys for their experiments. The sweepings were obtained from cases of from six months' to three days' duration after the onset of the paralysis. The following is a report of one of these experiments: August 29, they obtained the sweepings of a room wherein a 4-year-old child was stricken with poliomyelitis and was then two days paralyzed. In this room the child passed most of its time and also was there confined to bed. The dust, about 50

grams, was macerated overnight with 30 cubic centimeters of sterile water and then shaken for one hour. The mixture was filtered through a paper filter and 15 cubic centimeters of this filtrate were passed through a special Bougé filter under high pressure within an hour.

Within eighteen hours after the collection of this dust 5 cubic centimeters of the filtrate were injected into a monkey through the spinal canal after having first withdrawn 5 cubic centimeters of a clear spinal fluid and 8 cubic centimeters were injected subcutaneously. After the injection the animal was depressed and sullen and inattentive to its surroundings. On the following day the monkey was perfectly well and remained so until September 4, six days after the injection, when it was very ill and paralyzed. The animal presented the following symptoms: Flaccid paralysis in the right foreleg, which was hanging down from his side; he was unable to move it. There was a marked paresis of both hind legs, most pronounced in the left. He was able only with great difficulty to move about in his cage and this he accomplished by holding on to the bars with the left foreleg and hopping about. The patellar and plantar reflexes were absent. On extending the hind legs he shrieked, evidently from pain. He was chewing his food at times, but was rather sullen and depressed, keeping continually to a corner of his cage, holding on with his left forepaw, and lying down when unobserved. The muscles of his neck were not rigid, the pupils were normal and reacted to light promptly. A lumbar puncture was made repeatedly, but without success. Two drops of a gelatinous material were obtained from the needle, after withdrawing it from the spinal canal.

September 6, two days later, he still showed all the symptoms mentioned, but more marked, and still chewed his carrot. A spinal puncture was made and 2 drops of a gelatinous material obtained.

The animal was then killed and the following are the results of the autopsy: There was a marked hyperemia of the meninges in the lumbar region and a lesser one in the cervical region; the vessels of the brain cortex and cord were markedly congested. This hyperemia was evident at all the levels of the cord, in the medulla, the pons, the ventricles and basal ganglia. The cord and brain presented an edematous condition. On section, one could note hemorrhages in the gray substance of the cord, especially in the lumbar and cervical regions. There were also some hemorrhagic foci in the medulla, while the white and gray substance of the brain presented microscopically a normal appearance. The viscera presented the following changes: Areas of congestion in the middle and lower lobes of the left lung; the spleen was firm and congested, but not enlarged; the omentum was adherent to the cecum and all the visceral vessels were very much congested. All other organs and glands were, to all appearance, normal.

Sections of the spinal cord, cerebellum, pons, medulla, brain, spinal and basal ganglia were now emulsified in 50 cubic centimeters of normal salt solution and preserved for injections. The authors believe that they have thus proved that: Acute poliomyelitis is both infectious and contagious; that it is propagated by the dust, and that the nasopharynx must be the port of entry.

1 *Keratomalacia. S. Stephenson.
2 *Surgical Aspects of Acute Abdominal Disease in Childhood. H. S. Clogg.
3 Tuberculosis of Brain with Involvement of Both Optic Thalami. R. B. Ness and W. M. Elliott.

1. **Keratomalacia.**—Keratomalacia is essentially a disease of early infancy. The average age of Stephenson's thirty-one cases was four and one-half months. He has never seen the disease except in the children of the poor. The disease hardly ever occurs in breast-fed babies. Two alone of Stephenson's patients, or 6.46 per cent., were entirely breast fed. Syphilis was diagnosed clinically in seven, or in 22.58 per cent. Tuberculosis is an important cause of keratomalacia in infants. It existed in six, or 19.36 per cent. of the cases, the diagnosis being made during life in three and after death in three of the children. Of the twelve fatal cases tuberculosis was present in three. The disease was of the generalized type, as is usual in children so young with pulmonary or meningeal manifestations. Marasmus, pure and simple, accounted for seven, or 22.58 per cent. of the thirty-one cases. In two of the cases, or 6.45 per cent., the cause of the corneal mischief remained altogether obscure.

2. **Acute Abdominal Disease in Childhood.**—Clogg's own experience of ninety-eight cases of the "acute abdomen" in children under 12 years of age shows the diseases represented as follows: Appendicitis, fifty-four cases, pneumococcal peritonitis, six cases, inflammation of the diverticulum of Meckel, two cases, intussusception, twenty-eight cases, intestinal obstruction by a band, three cases, intestinal obstruction from adhesions, four cases, intestinal obstruction from pressure of mesenteric glands, one case. No case of gastric or duodenal ulcer came under his observation.

11. **Mayor's Scarf.**—Mayor's scarf consists of a square of stout material *measuring 40 inches across, folded obliquely*; 40 inches of an ordinary 3-inch bandage; a plug of carded cotton about 6 inches long and 3 or 4 inches thick; a dozen stout safety-pins. Place the plug of cotton in the arm-pit, bring the bent elbow close to the trunk and apply the base of the triangle formed by the scarf above the elbow, the apex being below. Draw it tight round the trunk and fix the ends of the scarf firmly at the back with safety-pins. The middle of the base of the triangle must not be opposite the arm, but nearer the middle line of the body, and the edge of the

scarf should cross the arm at the junction of the lower third with the upper two-thirds. If placed higher up it would press on the radial nerve and cause pain. The next step is to pass the two pendant corners of the folded scarf upwards beneath the elbow and forearm, placing one of them on each shoulder. Attach to these corners the ends of the bandage which, passing over the corresponding shoulders, is to be fixed to the scarf behind the trunk. Fix the layer of the scarf in front of the elbow to the layer behind it by means of a safety-pin placed in the angle formed by the forearm flexed on the arm. The hand can be placed in the gutter formed by the folded scarf or left outside as the patient may prefer. The latter is, on the whole, to be preferred, because it leaves the patient free to move the wrist and fingers. Mayor's scarf, as this apparatus is called, is said by Martin to be of the greatest service in quite a number of different conditions; for instance: (1) To immobilize the upper limb which is the seat of injuries to be attended to later on. It allows of the patient's being transported without undue pain. (2) In fractures of the clavicle, in which three indications are to be met: (a) The shoulder must be thrown outwards, for which purpose a cotton plug is placed in the axilla so as to serve as a fulcrum when the arm is brought close to the body. (b) External fragment is raised by raising the upper limb as a whole. (c) The internal fragment is lowered which can be done by applying a cotton or horse-hair cushion over this fragment; this is kept in position by placing it underneath the scarf bandage that runs over the shoulder and is fixed to the back part of the scarf, to which it is further secured by pinning it to the bandage. The apparatus must be frequently inspected in order to reduce the resulting deformity to a minimum. (3) In injuries to the shoulder in which the primary indication is to relieve the pain (fracture of the acromion or scapula). (4) To immobilize the shoulder when this joint is the seat of arthritis. (5) To fix the shoulder after reduction of dislocation. (6) In fractures of the upper end of the humerus: anatomic neck, head, fracture of the tuberosities in which early massage has to be employed, beginning on the sixth or seventh day. Pending recourse to massage and between the sittings the arm is maintained in position by the application of the scarf. Also in fractures of the humerus where there is no tendency to displacement. (7) For fixation of the elbow after reduction of dislocation of this joint; traumatism of the elbow without displacement of the fragments: fractures of the external or internal condyle of the humerus.

19. **Hereditary Protection Against Toxemia of Measles.**—The history of measles on Cape Clear Island for sixty-seven years is cited by O'Meara to show that immunity against the toxemia of measles is gradually acquired in insular communities where isolation is practiced. The first and subsequent epidemics in such communities can only be protective against future attacks of malignant measles in proportion to the numbers affected. This is what has occurred in Cape Clear, as the inhabitants during each epidemic isolated the cases as early as possible, and by this means always succeeded in preventing the outbreaks from becoming pandemic. Furthermore, the course of the disease during the past thirty years shows that this immunity is hereditarily acquired, the death-rate having fallen practically in proportion to the percentage of parents who had measles before marriage.

29 Abdominal Emergencies, Their Treatment and Prevention. J. Sherren.
30 *Investigation Into Effect of Pituitary Extract on Bowels After Abdominal Operations. L. A. Bidwell.

27. **Influence of Syphilis on Tuberculous Infections.**—According to Power children with heredo-syphilis often show signs of tuberculous disease of the joints in the form of a "gummatous" synovitis which does not improve beyond a certain point under treatment by antisyphilitic remedies. In young adults born of syphilitic parents an attack of pneumonia or other infective disease may be followed by signs of syphilitic inflammation (syphilis hereditaria tarda). The syphilitic lesions thus manifested may become tuberculous and the patient may die of tuberculosis. Adults who acquire syphilis while they are suffering from active tubercle are liable to have any preexisting tuberculous inflammations rendered much more active. It is to these persons that the generalization applies, "The tuberculous bear syphilis badly." Old persons who acquired syphilis many years previously may be attacked by senile tuberculosis. In such persons the disease runs a more chronic course than usual and there is less tendency to suppuration.

28. **Abdominal Emergencies.**—In his discussion of gastric ulcer Poynton says he is certain that early feeding on the lines of Lenhartz' method is practically and scientifically wrong. Post-mortems on six cases that he has had under his care have shown in each essentially the same feature, an open vessel in an ulcer which, acute or subacute, may or may not be in a healing stage. He sees no hope for success unless absolute rest is given to the stomach and allow the vessel to become sealed by clot. He allows nothing at all by the mouth, uses strict rectal feeding and water enemata, and limits abdominal movement with a binder.

30. **Pituitary Extract After Abdominal Operations.**—To discover how far pituitary extract, unaided by aperients, is able to restore peristaltic contractions after abdominal operations Bidwell tried its effect on twenty-one unselected laparotomies. In the first two cases the dose given was .5 c.c. This was commenced twelve hours after the operation, and given every four hours for three days. In the latter cases the dose was increased to 1 c.c. for adults; it was commenced about six hours after operation, and repeated every four hours until eight doses had been given. From the result of the injections in these cases it is evident that pituitary extract has a very marked effect on the muscular coats of the bowel, and that it is able to overcome the temporary paralysis due to exposure. This is shown by the early passage of flatus and by the absence of abdominal discomfort. In only three cases did the bowels act without the assistance of an enema, but in every case, except two, a satisfactory action of the bowels was obtained after a simple enema, and it was unnecessary to give any aperient by the mouth. All the patients passed flatus freely within a few hours of the first injection, and were free from any abdominal pain or distention; no patient complained of flatulence. The flatus was often passed freely without the introduction of a flatus tube. The pulse-rate remained much lower than usual, and after some of the severest operations it did not exceed 80 per minute. Except in the last two cases no patient suffered from postoperative retention of urine, and so catheterization was unnecessary. Bidwell says that the patients treated with injections of pituitary extract after abdominal operations are certainly more generally comfortable than those who do not receive them. He does not, however, consider that the drug can be relied on completely to empty the bowels without the assistance of enemata, and so he does not think that it need be employed after the first twenty-four hours. He would recommend three injections of 1 c.c. each during the first twenty-four hours as a routine practice after laparotomies; this will enable the patient to pass flatus freely, will prevent any flatulent distention, and will lessen the amount of aperient necessary for a thorough clear-out of the bowels. The injections must be made into a muscle, and should never be given subcutaneously, as the latter method causes considerable pain. The first injection should be given six hours after the operation, and the other two at intervals of six hours. No further injection need be given unless the patient complains of flatulent distention. He has never seen any unpleasant general symptoms follow these injections.

36. **Experimental Transmission of Goiter.**—McCarrison records his experiments made to test the assumption that goiter could be transmitted from man to animals by infected feces and at the same time determine the influence, if any, which earthworms might possess in spreading the disease. Sixteen goats were used in these experiments. The results in McCarrison's opinion prove that a hypertrophy of the thyroid gland of goats can be induced by infecting the water-supply with the feces of sufferers from goiter. It is, at present, impossible to state whether this hypertrophy is due to the action of the infecting agent of goiter, or only to the organic impurity of the water thus contaminated. Earthworms do not appear to be concerned in the spread of goiter. Goiter is essentially a disease of country localities, that is, of localities of unprotected water-supplies. In India McCarrison has found, from a study of the topography of a very large number of villages, that the freedom, or the reverse, of any particular village from this disease depends very largely on the extent to which the drinking water is contaminated by irrigating fields, which are fertilized with human and animal excreta. The source of the water-supply and the geological formations from which it is derived are, in comparison, of minor importance. Further experiments on goats are at present in progress, with a view to confirming the results detailed above. These experiments have not long been in progress, but already five out of twelve goats which are drinking fecally contaminated water show signs of enlargement of the thyroid, while no changes have occurred in the thyroids of twelve control animals. The final results of these experiments and the microscopic appearance of the glands will be detailed in a subsequent report.

37. **Reducing Action of Trypanosomes.**—The blood of certain animals in the later stages of trypansomal infections is frequently of a dark purple color. This appearance the authors claim results from deficient oxygenation of the hemoglobin. Living trypanosomes cause marked reduction of solutions of methylene blue and also of those of oxyhemoglobin. The incubation, in the absence of air, of living trypanosomes in defibrinated blood of a normal animal causes considerable reduction or, if the parasites be numerous, total disappearance of the oxygen combined with the hemoglobin. A correspondent increase in the amount of carbon dioxid has not yet been found. The mere presence of numerous parasites in the peripheral circulation is not, however, sufficient to account for the purple color of the blood, since the blood of rats and guinea-pigs swarming with parasites is usually of normal bright-red appearance. The purple color is most marked in the blood of rabbits in the later stages of the disease. Although the peripheral blood of these animals does not contain large numbers of parasites, yet the respiratory passages are found to be considerably involved. The nasal mucous membrane and that of the trachea and bronchial tubes is often extremely edematous and infiltrated, and the respiration of the animal is stertorous and labored. On microscopic examinations of sections of these tissues trypanosomes were often found in large numbers in the edematous mucous and submucous tissue.

41. **Suppression of Urine in Blackwater Fever.**—It is evident from the author's experiments that, under certain conditions, the mere passage of hemoglobin through the kidneys of a healthy animal is sufficient to cause suppression of urine owing to occlusion of the lumen of the renal tubules by plugs of granular material derived from the hemoglobin. The process is considerably facilitated by any factor which tends to lower the blood-pressure of the animal, and as a result the secretion of water by the Malphigian capsules. On the other hand, when the blood-volume of the animal is kept up by the injection of saline solution and by feeding the animal on moist food, a large amount of hemoglobin (38 gm.) may be injected without any tendency to suppression of urine.

42. **Organic Phosphorus Content of Various Diets and Diseases of Nutrition.**—The lack or deficiency of organic phosphorus in the diet is held by the authors to be the exciting cause of beriberi in the majority of cases. In other cases the differences may be individual in the patient, since some individuals require much larger amounts than others, and others may be unable to absorb and assimilate the compounds, though present in the diet. Occasionally, epidemics of beriberi appear to be due to a bacterial infection of the gastro-intestinal tract, either through the catarrh interfering with absorption or to the bacteria (or their products) absorbing or splitting the organic phosphates before they could be absorbed. Tropical beriberi is a disease of metabolism due to the amount of organic phosphorus compounds assimilated being below that essential for the human organism. This is in the majority of cases due to deficiency of organic phosphates in the diet, but may in occasional cases be due (a) to deficient absorption of organic phosphates by the alimentary tract, or (b) to bacterial infection possibly splitting the phosphates before absorption or interfering with the absorptive power of the intestine.

59 Novocain in Spinal Anesthesia in Urology. E. Jeanbrau.

44. **Endovesical Operations for Bladder Tumors.**—Doré and Mock describe the technic preferable under various conditions, comparing the methods of different operators, and reporting in detail seventy-six cases which they have compiled, including a large number previously unpublished. There was never any serious hemorrhage and the lesion soon healed. A point to be borne in mind is that as long as any clots remain in the bladder the organ contracts on them and this may keep up a tendency to hemorrhage. The patient should be reexamined every month the first year and after this at longer intervals. There was no recurrence of the tumor in 75 per cent. of the forty patients kept under supervision for two years.

45. **The Sexual Functions with Hypertrophy of the Prostate and After Freyer's Prostatectomy.**—Legueu and Papin report extensive clinical and experimental experiences, with numerous illustrations, and review eighteen cases in which the Freyer operation was done with necropsy later. They then review sixteen others on record in which the Freyer operation was done and sexual functioning thereafter recorded, with an additional group of nine cases from their own experience. In their nine cases the sexual functioning was unimpaired in all but two cases, and one of these was a man of 64. The anatomic and clinical data thus reviewed sustain the assumption that the Freyer technic does not interfere in the least with the genital functions, leaving this apparatus intact, ejaculation occurring exteriorly. By the relief from compression the operation may even rejuvenate the sexual functioning.

48. **Refractometric Estimation of Hydremia.**—This article is in the supplement of 186 pages which is issued in honor of the fact that the *Annales* is just entering its thirtieth year and of the Second International Congress of Urology held the same year. Widal opens the list of articles with a recommendation of the use of the refractometer as a means of estimating the dilution of the blood in chronic kidney and heart disease, supplementary to estimation of the degree of infiltration of the tissues by weighing the patient. By this means the action of drugs can be instructively studied, especially after the patient has been on a salt-poor diet for a time.

August 15, No. 16, pp. 497-528

62 Tracheobronchial Glandular Disease in Children. H. Grenet and M. Maillet.

61. **The Heart in Rheumatism in Children.**—Weill and Mouriquand say that even the apparently mildest rheumatism in a child, not causing the slightest appreciable symptoms, may yet entail heart trouble, possibly fatal. This is accepted as a matter of course in acute articular rheumatism, in which the heart behaves like a joint, but it is not generally known that a slight attack of rheumatism, with merely vague pains or none at all, may be followed after a few weeks or months or years by a little pain in the precordial region and dyspnea. The heart beat is found 120 or 140, but regular, and there may be evidences of old mitral insufficiency and recent pericardial friction sounds. The liver is slightly enlarged, the base of the lungs congested and the child is pale and languid, without appetite. Under rest in bed, ice to the heart, digitalis and the salicylates the symptoms subside and all seems well after four or five days. If the temperature is taken, however, it will be found a little above normal and after a few days the syndrome recurs, to subside and return again. This alternation of symptoms is characteristic of the affection in question. No one imagines anything is seriously wrong until the terminal phase develops with aggravation of all the symptoms, vomiting and hemoptysis and the child dies in collapse, without signs at any time of true asystolia, dropsy or edema. They have encountered ten cases of this malignant rheumatic heart disease in children and discuss its various features. Their experience teaches the importance of vigorous salicylic medication in every case of rheumatism in a child, no matter how apparently mild, and the physician should watch over the heart afterward. Every tachycardia, every pain in the heart region with or without fever, should be regarded as signs of serious trouble, especially when there is accentuation of the second pulmonary sound. This latter indicates not only the participation of the pericardium but also the possibility of deeper lesions so often associated with the pericarditis. Weill advocates subcutaneous injections of sodium salicylate dissolved in twice the amount of water. From 2 to 4 gm. of this solution can be injected at one point without inducing a local reaction. Digitalis also relieves; the children with the affection seem to display a special tolerance for digitalis and the symptoms improve under it.

67 * Tuberculosis. G. Bolognesi.

63. **Exclusion of Urine from the Bladder in Treatment of Local Bladder Tuberculosis.**—Willems gives an illustrated description of severe tuberculosis of the bladder persisting after nephrectomy. He made an opening into the remaining kidney in the lumbar region and diverted the urine by a rubber funnel and tube into a long, narrow rubber bag strapped to the inner side of the leg. The patient was a man of 30, whose vesical tuberculosis had persisted for five years and had confined him to bed for the last nine months with incessant tenesmus, so intense that he was unable to sleep. He was restored to comparative health at once and wore the urinal for ten months, enchanted with it. As soon as the course of the urine was diverted, the bladder began at once to heal and all trouble from this source was at an end, but a tuberculous process in the wrist continued to develop, as he refused to allow it to be treated properly. Fifteen months after the exclusion of the bladder the young man had a drinking bout and caught cold, a cough and fever developed with dyspnea and the amount collecting in the receptacle grew less and less and he soon succumbed in coma, the remaining kidney having become tuberculous, or it may have been already infected at the time of the operation. Necropsy showed that the severe bladder lesions had completely healed. Legueu reported a somewhat similar case last year in which he diverted the urine from the bladder by implanting the ureter of the remaining kidney in the intestine. All bladder trouble subsided at once and the intestine seems to bear without harm this new task to date, eight months after the operation.

67. **Conservative Treatment of Surgical Tuberculosis.**—Bolognesi has applied immobilization with local iodoform injections in forty-two cases of various surgical tuberculous processes and in twenty-one cases the lesions have entirely healed and in twelve there has been great improvement, but no benefit was realized in four and an operation became necessary in five. About twenty-five pages are devoted to tabulation of the details. The large joints, especially the knee, were the hardest to cure but seven were cured and four improved of the seventeen knee lesions and both of the elbow lesions.

75 Study by Centrifugation of Butter in Breast Milk. (Etude du beurre dans le lait de femme.) E. Planchu and R. Rendu.

74. **Flabby, Big Abdomen in Infants.**—Marfan refers to the enlargement of the abdomen from stretching of the atonic bowels plus a special flabbiness of the abdominal wall. Both these factors, the relaxation of the musculature of the digestive tract and of the walls enclosing it, are secondary to the

same cause which is producing the rachitis, as in nearly every case the pendulous belly is accompanied by signs of rachitic changes in the bones, and it forms part of what he calls the rachitic syndrome. Florid rachitis is often accompanied by atony of muscles. He believes that any infection or chronic intoxication occurring at a certain period of the development, this period extending from the latest months of intra-uterine existence to the end of the second year, is liable to entail rachitis; the most frequent of these causes are syphilis, tuberculosis and chronic digestive intoxication, but there are others. The infant reacts to these influences by changes in the cartilages and bone marrow, which interfere with normal ossification, and by changes in the blood and lymph-producing organs and in the glands, the latter possibly including changes in the parathyroids which may in turn induce tetany. The weakness of the muscles is another manifestation of the constitutional disturbance.

85 *Tuberculous Rheumatism. S. Veras.

78. **Club-Foot in Infants.**—Savariaud advocates a subcutaneous orthopedic operation for club-foot even in infants when it resists manipulations and the anterior portion of the calcaneus prevents even forcible correction. The ossification center must not be interfered with, so he aims to curet away mostly cartilage and encroach but very little on the bone. The bistoury is pushed down directly on and to the center of the head of the astragalus; then with a curet he scoops out chips from the cartilage and bone of the head of the astragalus and the greater process of the calcaneus. He sutures the skin or not after removing enough cartilage and bone tissue to permit ample and easy hypercorrection. A plaster cast is worn for several months, renewed every month or two. The feet thus operated on are remarkably supple and no recurrence is possible if the patient is supervised for a time. In three recent cases the infants were only 6, 12 and 15 months old, and the foot had been manipulated into a better position, much facilitating the operative correction for the deformity still left. The subcutaneous scooping out was preceded in each case by tenotomy and the end results are perfect in all, the children now wearing ordinary shoes. At first Savariaud hesitated to operate on the bone in such young children, but the excellent outcome and the harmlessness and simplicity of this subcutaneous technic have converted him to its advocacy. Broca endorses it only for cases in which there is reason to doubt the perseverance of the family in bringing the child regularly two or three times a week to the physician for proper orthopedic manipulations; they are liable alone to accomplish wonders in this line if systematically kept up. Jalaguier has been applying this subcutaneous scooping-out method for some time, and now has a record of ten cases, the ultimate outcome excellent in all. The children were a little older than in Savariaud's cases.

80. **Spasm of the Glottis as Only Sign of Tetany.**—Triboulet and Harvier state that even the Chvostek sign was absent in the case reported and there was nothing to indicate excessive nervous excitability except the spasm of the glottis. The child, an infant 13 months old, died from intercurrent measles pneumonia and the parathyroids were found extremely atrophied on one side while none could be found on the other. Triboulet suggests that spasm of the glottis occurring in this isolated form may have been responsible for the sudden death of certain children recorded as "thymus deaths." The assumption of an isolated spasm of the glottis throws light also on the persistence of symptoms after thymectomy for an unduly enlarged thymus. Electric tests of the excitability of the muscles will prove a valuable aid in differentiating the cause for a tendency to suffocation in children.

81. **Esophagoscopy in Children.**—Guisez reports a number of instructive cases to show the value of the esophagoscope in locating lesions, in facilitating the passage of sounds in cicatricial stenosis and permitting local treatment. Esophagoscopy is comparatively easy in children as the mouth of the esophagus is not closed, as in adults, but gapes rhythmically with inspiration. For a cicatricial stenosis he introduces a narrow bougie with the aid of the esophagoscope and leaves this bougie in place for a few hours. This prepares the way for sounds of a larger caliber and it is thus possible to stretch the lumen to normal size in time in most cases. If not, circular electrolysis through the esophagoscope renders invaluable service. He has had fifty-four patients with cicatricial stenosis resisting all ordinary measures. Only ten required gastrostomy; all the others were cured by the above measures through the natural passages. Twenty-one of the patients were children and all but two have been restored to a clinically normal condition.

82. **Anasarca with Intact Kidneys.**—The 2-months' infant began to lose weight and dropsy developed, the child dying in less than a month. There was nothing to explain the tendency to edema as the child was of healthy parentage and breast fed, and all the organs seemed sound. Necropsy revealed fatty degeneration of the liver while all the other organs were apparently sound and the kidneys intact.

84. **Diagnosis of Enlarged Thymus in Young Children.**—D'Oelsnitz analyzes the symptoms and signs suggesting hypertrophy of the thymus, his conclusions being that it is sometimes extremely difficult to distinguish between an unduly enlarged thymus and enlarged tracheobronchial glands as the cause of the dyspnea. He gives the details of twenty-one cases to illustrate the various points involved, including two in which he was certain that the thymus was hypertrophied, but an operation revealed atrophy of this gland, the enlarged tracheobronchial glands being responsible for the trouble. The special features of enlargement of the tracheobronchial glands are a history of measles, bronchitis or bronchopneumonia, the general lack of dulness over the manubrium, and difficulty in breathing which is experienced mostly during expiration, while the chest is retracted during inspiration, mainly in the lower portion, the depression occurring, if it occurs at all, simultaneously in the epigastrium, the lower sternum region and the hypochondrium on each side. The part of the chest above seems to protrude above the transverse groove resulting from this form of retraction. Sometimes the groove curves up on each side, so the chest above bulges spherically while the retracted portion below flattens out, spreading out on the sides. Roentography shows the normal chest with a shadow like a long-necked bottle, while with enlarged thymus the shadow is irregular, with a protrusion just below the neck of the bottle on one or both sides, but the outline is smooth and the shadow even. With swollen lymph-nodes in the anterior mediastinum, the upper part of the shadow is as normal but below it spreads out irregularly, generally on the right side of the shadow of the heart, the protrusions small and round or finger-shaped, sloping down and outward, sometimes showing several shadows with a circular outline while the depth of the shadow may vary from that of the heart, being either lighter or darker. He gives twenty typical radiographs to show the various features in these different conditions, regarding radiography as indispensable. The dulness with enlarged thymus usually encroaches on the left side.

85. **Tuberculous Rheumatism.**—Veras reports from Smyrna three cases of rheumatic pains in one or more joints in children giving positive tuberculin reactions. The pains dragged along for years without ever reaching the intensity of acute rheumatism, and the arthritis apparently healed, too soon

to accept an ordinary tuberculous process, while the conception of a simple inflammatory process amply explains the facts observed.

90 Primary Multiple Tumors in Bones. E. Pallasse, C. Roubier and A. Goyet.
91 *Operations on Cervical Sympathetic for Exophthalmic Goiter. A. Chalier. Continued.

88. **Painful Nephritis.**—Rochet reports ten cases in which he operated on the kidney to relieve intense pain in the course of nephritis, with or without pus. He reviews the pathologic findings when the kidney was exposed and the technic appropriate for each nephrolysis, decapsulation, nephrotomy or nephrectomy. The operation put an end to the pain permanently in all the cases, although the later after-history is not known in one instance.

89. **Fracture of the Leg from the Standpoint of Industrial Insurance.**—Imbert expatiates on the revolution in regard to fractures of the leg that has followed the legislation on compensation to working-men for accidents while at work. The aspect of the leg afterward is not considered now, the main point being to restore normal functioning, the legs being extremely important not only for walking but in bearing burdens while the workman has to keep his balance on ladders and scaffolds—function for a day laborer requiring an elasticity and strength not needed by persons of more sedentary occupations. Imbert discusses the various points to be borne in mind and how to prevent persisting pain, shortening, muscular atrophy and stiffness. These various elements of persisting incapacity deserve more careful study, and he warns that the physician should beware of asserting that the patient is quite cured; he must not forget that various lesions engendered by a fracture are durable and sometimes persist indefinitely.

91. **Operations on Sympathetic Nerve for Exophthalmic Goiter.**—Chalier here continues his review of the operations performed by Jaboulay for this purpose and of the end-results. Of the total thirty-one operations, twenty-four of the patients have been reexamined from eight months to fourteen years after the operation and three were found completely cured, nine very much improved, and six may be classed as semisuccessful operations, of the eighteen whose complete history is known. These experiences show that an operation on the cervical sympathetic not only arrests the disease but is liable to be followed by retrogression of the affection amounting to a complete cure. In every patient the most distressing symptoms were mitigated or entirely cured; even those least improved were no longer sick but merely delicate. With a few simple precautions they were able to avoid all functional disturbances, such as palpitation and dyspnea, without need for medication. Even in the least favorable cases, there was manifest improvement sooner or later even after a number of months. The operation has a constant action on the ocular and nervous disturbances; the heart disturbances and the goiter are frequently modified but less regularly and in a less pronounced manner. One interesting effect is a rapid improvement in vision when there had been preceding myopia.

Only eight of the thirty-one patients were men; the age ranged from 17 to 66. Six of the patients died soon after the operation, but in the last ten years there has been no fatality from these operations on the sympathetic. In four of the six deaths, complications on the part of the lungs were responsible for them; another patient succumbed to erysipelas of the face, its fourth recurrence, and the sixth patient died with signs of sudden suffocation, not explained until necropsy revealed a very large and adherent thymus. Ten patients have died during the years since, one from chronic diarrhea, one from heart disease, five from tuberculosis—all intercurrent diseases occurring while the patients were rejoicing at being freed from their exophthalmic goiter. The three other fatalities followed an operation on the thyroid intended to supplement the operation on the cervical sympathetic and complete a radical cure. These cases confirm anew the danger of operations on the thyroid in exophthalmic goiter even for patients immeasurably improved by sympatheticectomy.

September 2, No. 70, pp. 705-712

102 Antityphoid Vaccination in the Army. (Sur l'emploi facultatif de la vaccination antityphique.) L. Landouzy.

101. **Hysteric Hip Disease.**—Broca analyzes the features of four typical cases of pain and lameness in the hip joint of hysteric origin, emphasizing the special differential points. Among these is the lack of any difference between the aspect of the two hips and lack of the compensating processes in the pelvis and spine when the limb is flexed. Also the possibility of flexing the limb when the patient's attention is diverted and the physician gently and very gradually flexes the knee on the abdomen. The patient seems to feel a pinching of the skin as painful as forcible pressure on the head of the femur. In one of these cases, the patient, a 10-year-old girl, had pronounced adduction and flexion of the left leg. Seated on the edge of the table, there was no trace of scoliosis. She was unable to walk, but the physician told her that this was because her knee had lost its strength and bends, and that she could walk if her knee was held stiff. Holding the knee stiff he encouraged her to take a few steps which she found she could do without pain as long as the knee was held quite stiff, and she was kept walking while he gradually ceased to hold the knee without her perceiving this. When she found that she was walking without aid the cure was complete. Inquiry in the environment of such cases always revealed some one with a hip affection causing lameness and pain, and there was generally a history of some old slight affection involving the hip or leg. In the above case there was a trace of atrophy of the muscles, possibly relics of some torpid paralysis in early life, and subconsciously calling attention to that limb. Another differential point in hysteric coxalgia is the instability of the tender points and the inconsistency between the intensity of the pain on slight contact while forcible deep pressure may be unnoticed. The tranquil expression in comparison with the intensity of the pain, the peaceful sleep at night with none of the paroxysmal cries during slumber of organic disease, and the fact that when the lame child is told to stop she rests on whichever leg she happens to be standing on at the time—all these suggest hysteria. Another sign is that the child keeps the affected knee stiff when asked to pick up something from the floor, while the hip is bent without effort. The little patients do not know that this

is the reverse of what occurs with organic disease. In one of the cases described true organic disease was accompanied by hysteric lameness and pain but radiography and examination under chloroform gave negative organic findings until the head of the femur broke through. In treatment of hysteric coxalgia, Broca warns against any suggestion that treatment will have to be long continued, and he warns especially against immobilization. When the confidence of the patient is gained, the cure predicted by some slight brief treatment is soon realized, and the hospitals witness many cases of such instantaneous cures of both hip and pelvis trouble.

106 and 108. **Tumor in Placenta.**—Kummer has found records of seventy-eight cases of a tumor in the placenta and reports another. Pregnancy and delivery had been apparently normal and the child was healthy except that it looked unusually yellow at first. A large fibroma-angioma was found in the placenta. In sixteen of the forty-six cases on record in which the pregnancy progressed nearly to term, there was spontaneous premature delivery. Kraus found mention of hydramnion in nine of his fourteen cases. Asphyxia was common among the children and cardiac defects and kidney trouble in the women.

Hauser has encountered two cases of a benign tumor in the placenta in a comparatively short time. In the present case the tumor had a capsule and the patient was a syphilitic young woman. Delivery was apparently normal at term but the child died within a month.

110. **Vaginal Tuberculosis.**—In Mauler's four cases the vagina had evidently become infected from tuberculous lesions in the genitals above. All four cases were encountered within six months although for years he had been seeking in vain for an instance of vaginal tuberculosis.

111. **Pelvic Presentation.**—In the course of this dissertation on a number of minor points useful to bear in mind, Bayer remarks that he seldom makes use of the Schultze swinging method now; his experiences with it have been discouraging as, for instance, in a case in which a child born with great difficulty in pelvic presentation had been revived after long and tedious blowing air into its lungs. It was breathing spontaneously and whimpering when he thought he would complete matters by swinging it twice, but the child died *at once.*

122 [illegible] Arterial Circulation for the Kidney. (Ausbildung eines arteriellen Collateralkreislaufes der Niere.) M. Katzenstein.

113. **Glycosuria After Removal of the Pancreas.**—Eppinger and Falk report extensive experimental research with animals fed monoacetyl glucose and other ester compounds of grape sugar with acetic acid or saccharids before and after removal of the pancreas. They show that the assimilation of grape sugar may be profoundly modified while the assimilating power for some of these saccharids may be unimpaired, even after removal of the pancreas. The research suggests that it may be possible to find useful articles of food among these substances, especially for diabetics.

118. **Influenza in Infants.**—Müller refers in particular to influenza assuming the form of sepsis or effusion in the serous cavities of the body. In the septic form the fever sets in high but alternates with subnormal temperature; no disturbance in any organ can be discovered and the general health does not seem to be much disturbed in the majority of cases. In a few cases in his experience, however, the sepsis proved rapidly fatal or the whole syndrome recurred again and again with free intervals of weeks and months. He gives the curves of three such cases. In three others the influenza developed as a pleural empyema; the only infant less than six months old who survived was the only one merely punctured. No attempt at tamponing was made until the symptoms were much mitigated; the suppuration persisted for weeks but the child finally recovered. In three other cases the effusion occurred in the peritoneum and the children succumbed with signs of septic peritonitis. In some cases the symptoms indicated a serous meningitis.

119. **Operative Treatment of Laryngeal Tuberculosis.**—Blumenthal comments on the serious outlook when swallowing becomes so painful that the patients with laryngeal tuberculosis do not get enough nourishment and become intensely depressed. He has succeeded in putting an end to the dysphagia in two cases by resecting the superior laryngeal nerve. He describes the comparatively simple technic, applied to a woman of 33 and a man of 36 as a last resort. The by-effects were slight and transient.

127. **Technic for Illumination of the Nasal Sinuses, Orbit and *Middle Ear.***—Gyergyai uses an electric lamp, the holder bent sideways at a right angle, this branch being long enough to be introduced to the depths of the maxillary sinus, close to the ear. He has applied it in thirty-eight cases and has been amazed at the instructive oversight thus permitted.

128. **Relations Between Mouth-Breathing and Pulmonary Tuberculosis.**—Rosenberg states that, besides its more familiar evils, chronic obstruction of the nose modifies the respiration in a way that materially favors bacterial invasion. The bacilli not only get into the lower air passages more readily but they find more favorable conditions for colonization, especially in the non-tuberculous shriveling of the right apex which is so common in mouth-breathers, called by Krönig "collapse induration." Rosenberg found this induration at the apex in eighteen of fifty cases of chronic obstruction of the nose, although there was nothing to suggest tuberculosis. Such persons are predisposed to tuberculosis on account

to accept an ordinary tuberculous process, while the conception of a simple inflammatory process amply explains the facts observed.

112 Relations Between Proliferation of Fetal Cells and Puerperal Involution of the Uterus. (Beziehungen der fötalen Zellwucherungen zur puerperalen Rückbildung des Uterus.) G. Schickele.

106 and 108. **Tumor in Placenta.**—Kummer has found records of seventy-eight cases of a tumor in the placenta and reports another. Pregnancy and delivery had been apparently normal and the child was healthy except that it looked unusually yellow at first. A large fibroma-angioma was found in the placenta. In sixteen of the forty-six cases on record in which the pregnancy progressed nearly to term, there was spontaneous premature delivery. Kraus found mention of hydramnion in nine of his fourteen cases. Asphyxia was common among the children and cardiac defects and kidney trouble in the women.

Hauser has encountered two cases of a benign tumor in the placenta in a comparatively short time. In the present case the tumor had a capsule and the patient was a syphilitic young woman. Delivery was apparently normal at term but the child died within a month.

110. **Vaginal Tuberculosis.**—In Mauler's four cases the vagina had evidently become infected from tuberculous lesions in the genitals above. All four cases were encountered within six months although for years he had been seeking in vain for an instance of vaginal tuberculosis.

111. **Pelvic Presentation.**—In the course of this dissertation on a number of minor points useful to bear in mind, Bayer remarks that he seldom makes use of the Schultze swinging method now; his experiences with it have been discouraging as, for instance, in a case in which a child born with great difficulty in pelvic presentation had been revived after long and tedious blowing air into its lungs. It was breathing spontaneously and whimpering when he thought he would complete matters by swinging it twice, but the child died at once.

122 Possibility of Collateral Arterial Circulation for the Kidney. (Ausbildung eines arteriellen Collateralkreislaufes der Niere.) M. Katzenstein.

113. **Glycosuria After Removal of the Pancreas.**—Eppinger and Falk report extensive experimental research with animals fed monoacetyl glucose and other ester compounds of grape sugar with acetic acid or saccharids before and after removal of the pancreas. They show that the assimilation of grape sugar may be profoundly modified while the assimilating power for some of these saccharids may be unimpaired, even after removal of the pancreas. The research suggests that it may be possible to find useful articles of food among these substances, especially for diabetics.

118. **Influenza in Infants.**—Müller refers in particular to influenza assuming the form of sepsis or effusion in the serous cavities of the body. In the septic form the fever sets in high but alternates with subnormal temperature; no disturbance in any organ can be discovered and the general health does not seem to be much disturbed in the majority of cases. In a few cases in his experience, however, the sepsis proved rapidly fatal or the whole syndrome recurred again and again with free intervals of weeks and months. He gives the curves of three such cases. In three others the influenza developed as a pleural empyema; the only infant less than six months old who survived was the only one merely punctured. No attempt at tamponing was made until the symptoms were much mitigated; the suppuration persisted for weeks but the child finally recovered. In three other cases the effusion occurred in the peritoneum and the children succumbed with signs of septic peritonitis. In some cases the symptoms indicated a serous meningitis.

119. **Operative Treatment of Laryngeal Tuberculosis.**—Blumenthal comments on the serious outlook when swallowing becomes so painful that the patients with laryngeal tuberculosis do not get enough nourishment and become intensely depressed. He has succeeded in putting an end to the dysphagia in two cases by resecting the superior laryngeal nerve. He describes the comparatively simple technic, applied to a woman of 33 and a man of 36 as a last resort. The by-effects were slight and transient.

132 Roentgen Rays in Estimation of Gastric Acidity. (Zur Aziditätsbestimmung des Mageninhalts mittels des Röntgenverfahrens.) G. Schwarz.

127. **Technic for Illumination of the Nasal Sinuses, Orbit and Middle Ear.**—Gyergyai uses an electric lamp, the holder bent sideways at a right angle, this branch being long enough to be introduced to the depths of the maxillary sinus, close to the ear. He has applied it in thirty-eight cases and has been amazed at the instructive oversight thus permitted.

128. **Relations Between Mouth-Breathing and Pulmonary Tuberculosis.**—Rosenberg states that, besides its more familiar evils, chronic obstruction of the nose modifies the respiration in a way that materially favors bacterial invasion. The bacilli not only get into the lower air passages more readily but they find more favorable conditions for colonization, especially in the non-tuberculous shriveling of the right apex which is so common in mouth-breathers, called by *Krönig* "collapse induration." Rosenberg found this induration at the apex in eighteen of fifty cases of chronic obstruction of the nose, although there was nothing to suggest tuberculosis. Such persons are predisposed to tuberculosis on account

of this local change at the apex. If it is diagnosed as a mild tuberculous process and the patient is sent to a sanatorium for tuberculosis, he is almost certain to contract the disease which otherwise he might have escaped. Such cases explain the negative tuberculin reaction in some of the supposed tuberculous inmates of sanatoriums and the change to a positive reaction later. The obstruction in the nose may be the result of adenoids but deformity of the septum and hypertrophy of the turbinate bones may sometimes be incriminated. Rosenberg cites in conclusion Blümel's experience at the Görbersdorf sanatorium with seventy-five non-tuberculous inmates among the total 1,700 supposedly tuberculous; he discovered twenty-eight cases of this collapse induration in this group of seventy-five. From the Belzig sanatorium it has been reported that nasal affections were found in 84 per cent. and throat affections in 76 per cent. of 120 patients examined. Rivers in England in examining 500 persons found twice as many mouth-breathers among the consumptives as among the non-tuberculous. Rosenberg pleads in conclusion for prompt measures to relieve nasal stenosis and thus ward off these perils.

129. **Peritonsillitis.**—Levy remarks that with this affection the objective signs may be insignificant, especially when it is a recurrence. The first sign is usually slight protrusion of one tonsil. Palpation from without is often instructive; the glands may be swollen on both sides, even when the peritonsillitis involves but one side, and the glands may be very tender. The radiating of the pain to the ear is a constant and early symptom. The general symptoms are by no means so pronounced as with follicular tonsillitis, although there may be chill and some fever; the disturbance in swallowing is generally all the patients complain of. This with the limitation to one side generally differentiate the trouble. His experience with sixty cases showed that early incision had no effect in 33 per cent. of the cases, and he now waits for demarcation as a rule unless the pain is severe. In recurring peritonsillitis the supratonsillar fossa is generally the source of the trouble, and excision of the upper lobe of the tonsil puts an end to all disturbances. It is not necessary to remove the whole tonsil, he says.

143 *Actinomycosis of the Bronchi. (Chronische Bronchialerkrankungen mit Ausschluss der Tuberkulose. XII.) A. Posselt. Commenced in No. 35.
144 Changes Undergone by Iodin Preparations in the Stomach and Upper Duodenum. L. Metzger.
145 Keratoma Palmare and Vitiligo. W. Friedländer.

134. **Dilatation of the Esophagus.**—Jüngerich thinks that greater attention should be paid to the neurasthenia underlying the dilatation of the esophagus in most cases. He relates his experiences with six patients, all but one being men between 24 and 56. Symptomatic treatment is necessary, repeated on recurrence of trouble. It is thus possible to keep the patients free from disturbances for many months at a time, even when a complete cure is not possible. The spasm of the cardia responsible for the trouble generally comes on suddenly; the frequent remissions of longer or shorter duration are characteristic, as also the alternation with spastic phenomena elsewhere and the impossibility of introducing the sound beyond the cardia at times, while at other times it slips smoothly in.

137. **Fleas and Flea Traps.**—Harms discusses the biology and natural history of the flea family and illustrates a little flea trap in common use in the Orient. It consists of a small stick smeared with a sticky substance, the stick inserted in a strip of bamboo, the sides cut out to leave only seven narrow strips. It acts on the principle of sticky fly paper, the bamboo shell keeping the sticky tube from contact with the clothing. The Chinese are said to strew a number of these tiny traps around the bed and wear them in their clothes.

139. **Medical Treatment of Gastric Ulcer.**—Glaessner estimates that only about 25 per cent. of patients with gastric ulcer are ever permanently cured by internal measures alone. He also calls attention to the fact that any gastric juice with an actual digestive action can maintain ulceration in the stomach: hyperacidity is not encountered oftener than in 43 per cent. of the cases with gastric ulcer. Study of the end-results after gastro-enterostomy has convinced the investigators that the benefit from this operation is due exclusively to the reflux of bile and pancreatic secretion into the stomach, thus washing the ulcer with bowel content. This, in connection with the regurgitation of intestinal juice into the stomach after pouring in oil and the benefit therefrom in gastric ulcer, suggests that internal administration of an artificially prepared intestinal juice might have a powerful curative action on gastric ulcer. Glaessner reports experimental research which confirms these views, even a 0.2 per cent. concentration of bile inhibiting digestion *in vitro*, notwithstanding the presence of large amounts of hydrochloric acid. He thinks these facts open new horizons for internal treatment of gastric ulcer.

143. **Actinomycosis of the Bronchi.**—Posselt expatiates on the extreme importance of an early diagnosis as in few affections is treatment so effectual. He reviews extensive experiences of his own and others; they show among other things that the apex of the lungs is occasionally the primary seat but that the bronchi are more often involved. The affection may attack children or adults and there is a comparatively harmless pseudoactinomycosis sometimes observed in the tonsil. Repeated examination of the nasopharynx and of the sputum may be necessary before the true origin of the bronchial affection is discovered, and he is convinced that systematic microscopic examination of the sputum in rural districts would show the disease to be far more frequent than is generally supposed; serologic methods may also aid in the differentiation. Once diagnosed, he gives potassium iodid and calls the surgeon at once, radiography pointing the way to effectual measures. Karewski insists that actinomycosis should be suspected in all cases of slowly developing swellings in the chest, especially in the rear and when preceded by signs of bronchitis, and a tuberculous process can presumably be excluded. He advises operative removal as bound to be successful in the early stages without metastasis.

Münchener medizinische Wochenschrift

August 29, LVIII, No. 35, pp. 1849-1896

152 Influence of Deficient Oxygen on Blood Production. (Blutvermehrung durch Sauerstoffmangel.) E. Kuhn.
153 Anilin Poisoning. (Beitrag zur Anilinvergiftung.) W. Friedländer.

146. **Polycythemia.**—Bergmann and Plesch give the tabulated findings in three cases of polycythemia examined with the same detail as Senator's patient. They are inclined to regard the polycythemia as a compensating process in some cases.

148. Hydrocephalus in Obstetrics.—Rieländer discusses the various modes in which hydrocephalus may interfere with delivery, and the diagnosis of this anomaly in time at the birth. The main point in diagnosis is for the accoucheur to bear the possibility of hydrocephalus in mind. It is so rare an occurrence that it is seldom thought of as the explanation of the dragging of the birth, but it should be suggested when the head at the pelvic inlet is unusually broad with wide fontanelles and sutures which have a cystic feel. Or when the head shows no tendency to enter the pelvis even with vigorous contractions of the uterus. But one or the other of these three signs and all others mentioned in the textbooks may be lacking, as he shows by three typical cases described in detail. Only careful examination, eventually under general anesthesia, and careful weighing of the different symptoms will permit a true diagnosis. Treatment is very simple, merely to allow escape of the fluid by puncturing the fetal brain. Hammerschlag in his manual published last year stated that 20 per cent. of the mothers succumb—13 per cent. from rupture of the uterus and 7 per cent. from infection. The diagnosis is most difficult when the head presents first; the ineffectual labor keeps up for days, the accoucheur waiting while the impatient midwife keeps repeating her local examination. The uterus then ruptures or the woman's temperature rises. A history of hydrocephalus at a previous birth may be instructive.

151. Evacuation of Pleural Effusion.—Jacobaeus thinks that it is extremely important to remove the last traces of a pleural effusion, especially if it is purulent, and he has accomplished this in ten cases by the simple technic described. He introduces a trocar wide enough to permit the passage of a cystoscope through it. The trocar is inserted above the ninth interspace and most of the effusion is evacuated through it, air entering as the patient breathes, replacing the effusion. He then introduces through the trocar a small, soft ureter catheter, the tip weighted with lead. The air escapes readily between the walls of the catheter and the trocar, while the weighted tip drops to the lowest portion of the chest, and the last traces of the effusion can thus be aspirated. If there is thick pus, he pours in salt solution through the catheter and has found it useful to rinse out the cavity in this way in conclusion.

158 *Tube Speculum for Inspecting Peritoneum. (Das röhrenformige Spekulum bei der Bauchfellentzündung.) F. Kuhn.
159 *Technic for Closing the Intestine. (Zur Technik des operativen Darmverschlusses.) T. Voeckler.
160 Roentotherapy of Rhinoscleroma. A. R. v. R. Rydygier.

158. Speculum for the Peritoneum.—Kuhn has been using for some years a small tube speculum on the principle of those used for the vagina and rectum, and here expatiates on the instructive oversight thus obtainable. He introduces the speculum with an obturator, repeatedly withdrawing the latter and replacing it before proceding farther, or introducing a rectoscope lamp into the speculum. It is thus possible to inspect the small pelvis and the region behind the stomach, etc., as well as the different parts of the inflamed peritoneum. He always proceeds on the principle that the speculum must enter from a non-infected region, using a separate speculum at each point. A drain can be introduced through the speculum and left as the latter is withdrawn. To prevent inclusion of omentum, he sometimes covers the top of the drain with a layer of gauze. The small incisions, each containing its speculum, permit irrigation without pressure and prevent distention of the abdominal walls. He sometimes uses a more flaring speculum, open along one side, which permits introduction of an instrument.

159. Operative Closure of the Intestine.—The stump is tied with a single knot, like a rowboat hitch, untied by pulling on the longer end. The tied stump is then pushed in and the intestine drawn together over it with an ordinary purse-string suture. The first knot is then untied, leaving the invaginated stump free, without any dead space or burying of a foreign body or injury from the necrotic circle where the gut had been tied.

166 "Three-Day Fever" in Catania. G. De G. Giunta.

Policlinico, Rome

August 27, XVIII, No. 35, pp. 1097-1128

167 *Influenza in Pregnancy and the Puerperium. U. Rosi.

September 3, No. 36, pp. 1129-1160

168 *Hypophysis Treatment of Exophthalmic Goiter. (La cura ipofisaria del morbo di Basedow.) A. Salmon.

167. Influenza in Pregnancy and Puerperium.—Rosi has encountered fourteen cases of influenza in pregnant women and seven parturients with influenza. The fetus may be injuriously affected and the pregnancy may terminate prematurely or persist unduly long. Differentiation is important, especially in the puerperium, to avoid errors in treatment.

168. Hypophysis Treatment in Exophthalmic Goiter.—Salmon reports two cases, the patients women about 45; systematic hypophysis treatment induced such marked improvement that he regards this method of treatment as based on a sound basis, similar to the efficacy of thyroid treatment in deficient thyroid functioning.

Riforma Medica, Naples

August 28, XXVII, No. 35, pp. 953-980

169 Hypertoxicity of the Stool in Pneumonia. G. Breccia.
170 *Picric Acid for Sterilization of the Skin. (Dei recenti metodi di disinfezione della cute e di un nuovo metodo con soluzione alcoolica di acido picrico.) A. Fontana.

170. Sterilization of the Skin with Picric Acid.—Fontana uses a 1 per cent. alcoholic solution of picric acid for sterilization of the field of operation, and extols its advantages over other methods. It is as effectual, his tests seem to show, as the tincture of iodin method while it is much more convenient for sterilization of the hands. Both of these methods do away with the long scrubbing indispensable with other technics and which is so liable to chill the patient.

Hospitalstidende, Copenhagen

July 26, LIV, No. 30, pp. 825-856

171 *Gangrene in Infectious Diseases. K. M. Andersen.

171. Gangrene with Infectious Diseases.—Andersen's patient was a little girl who had gangrene of the leg about six weeks after the onset of an apparently mild scarlet fever. The progress of the gangrene compelled amputation while a superficial patch of gangrene on the thigh above healed. He has been able to find only five cases on record of gangrene complicating scarlet fever, but ninety-eight cases in which gangrene developed with other infectious diseases or lesions. Emboli were found only in eleven cases, autochthonous thrombi being responsible for the balance. He discusses the mechanism of the gangrene and in conclusion reports a case of gangrene in the course of osteomyelitis of the femur but the lesion healed in the course of a month. The trouble in both his cases was evidently the result of toxic changes or inflammation in the afferent vessels.

Norsk Magazin for Lægevidenskaben, Christiania

September, LXXII, No. 9, pp. 937-1000

172 Two Cases of Infantile Scorbutus. C. Looft.
173 *Test for Bile in the Blood. (Galdereaktion i blodserum til klinisk bruk.) A. Sunde.
174 Chromocystoscopy. N. Friis.

173. **Simple Test for Bile in the Blood.**—Sunde has found that it is possible to estimate the intensity of the admixture of bile with the blood with sufficient accuracy for all practical purposes by the length of time necessary for the color reaction to occur when the serum is treated with nitric acid. He has been thus testing the serum from seventy patients and comparing the findings with those from other tests. He used Scheel's modification of Gilbert's test, adding to 20 or 30 drops of the blood-serum, in a test-tube not over 10 mm. in diameter, a little of the reagent made by combining 300 parts nitric acid with 0.06 parts sodium nitrite. The reagent is allowed to flow down the side of the tube and a bluish ring forms at the junction of the two fluids. The interval before the bluish ring becomes evident varies from half a minute to thirty minutes when there is considerable bile in the blood, while with only small proportions the interval ranges from forty-five to sixty-five minutes or longer. It is possible thus to distinguish the pathologic from the non-pathologic cases; the shorter the interval the greater the probability of some local affection in the liver or bile passages interfering with the normal evacuation of the bile. In one case with colic suggesting gall-stones and a slight tendency to jaundice, the reaction occurred in ten minutes and a biliary lesion was assumed; but the urine findings pointed to pyelitis and radiography revealed large calculi in both kidneys. The enlarged right kidney in this case may be compressing the bile passages and thus inducing the cholemia indirectly, with intact biliary apparatus, but, more probably, the tendency to lithiasis involves both the bile and the urine systems.

AN EXTRA-ABDOMINAL MULTILOCULAR OVARIAN CYST *

THOMAS S. CULLEN, M.D.
BALTIMORE

Several months ago, Dr. Frank R. Smith asked me to see a woman who had a kidney-shaped tumor slightly below and to the right of the umbilicus. The patient had noticed a small lump in this situation several years before, which for a long while had remained quiescent but during the last year had gradually increased in size. At operation it was found to be a partly solid, partly cystic tumor of the ovary lying external to the abdominal muscles, the tumor and its surrounding sac being covered over with a small amount of adipose tissue and the skin. The pedicle of the tumor passed through a hernial ring to the outer side of the right rectus and obliquely across the lower abdominal cavity to what corresponded to the normal insertion of the right utero-ovarian ligament.

I have been unable to find any reference to a similar case in the literature.

History.—Mrs. M. W., aged 56, was a short, well developed woman, and, apart from a tumor mass in the lower abdomen, was in excellent health. She had had eleven children. Her periods had ceased at 50. She had felt some pain in the right ovarian region for fifteen years, and for about ten years she had noticed a little tumor situated in the right lateral abdominal wall slightly above a line drawn between the umbilicus and the anterior superior spine. This, from her description, seemed to have been about the size of an ovary. During the last ten months this small lump had increased in size until it formed a lobulated mass, elongate in form, about 10 by 8 cm. It seemed to be but a short distance beneath the skin and could be lifted up to some extent in the hand, but its absolute relationship could not be determined on account of the presence of a considerable amount of adipose tissue.

Operation.—Nov. 1, 1910, on making a pelvic examination, under anesthesia I found that the uterus was normal and that there was no thickening laterally. Not being sure of the exact condition, I made a median incision. The uterus was normal, the left tube and ovary presented the usual appearance. The right tube showed no change, but the right utero-ovarian ligament was markedly drawn out into a band about 1 cm. broad. This led to a hernial opening with smooth margins in the right lateral abdominal wall below and to the right of the umbilicus, but at least 12 cm. from the inguinal region (Fig. 1). After obtaining good exposure I found that this flattened band of the utero-ovarian ligament passed directly into a hernial opening about 2.5 cm. in diameter, and into this opening a finger could readily be introduced. The intra-abdominal portion of the pedicle was clamped off and sutured. An incision was then made over the prominent part of the abdominal tumor, which proved to be extra-abdominal. The more prominent part of this tumor lay directly beneath the skin in the adipose tissue, and was very easily freed by blunt dissection to the point where the hernial ring entered the abdomen. I then cut the *peritoneum around the hernial ring and delivered the tumor,* with its peritoneal covering intact. The space where the tumor had existed having been obliterated and the inner incision having been sutured, the outer wound was also closed. The ovarian tumor was multilocular.

There had evidently been a hernial protrusion through the right lateral abdominal wall, into which the ovary had dropped and remained for several years. During the last year it had increased in size and given rise to a multilocular ovarian cyst. Naturally with the increase in size, the escape of the ovary from the sac was impossible.

Macroscopic Examination of Hardened Specimen (Path. No. 15,723).—The hernial opening was about 2.5 cm. in diameter. Its margins consisted of peritoneum, outside of which was a zone of adipose tissue. The tumor itself was kidney-shaped (Fig. 2) 12 cm. long, 7 cm. broad, and 6 cm. in thickness. It was covered everywhere with peritoneum, which could be readily separated from it. Here and there attached to the outer surface of the peritoneum were tags of adipose tissue. The tumor itself was in large measure solid, resembling a fibroma. It presented a lobulated appearance. Here and there between nodules it showed cystic spaces, oblong, irregular, or round, varying from 2 mm. to 2 cm. in diameter. The majority of these were transparent and contained clear fluid. Some of them were slightly blood-tinged. So much could be made out through a window, which was cut in the peritoneum. On peeping in through the hernial ring, were seen cysts varying from 2.5 cm. to 3 cm. in diameter and apparently filled with clear fluid. After the drawing had been made the tumor was cut in two. The appearance on section is well shown in the drawing in the right upper corner of Figure 2.

Histologic Examination.—The solid portion of the tumor consisted in large part of fibrous tissue containing triangular or spindle-shaped nuclei. In some places the nuclei were abundant, in others scanty in number. The tissue showed a considerable degree of hyaline degeneration. At one or two points characteristic ovarian stroma was still in evidence. No Graafian follicles could be found, but after an examination of numerous sections a typical corpus fibrosum was noted. In some sections a few bundles of non-striped muscle were visible. The stroma had a meager blood-supply except in a few areas, where there were groups of rather large veins.

Scattered sparingly through the stroma were small circular or irregular glands occurring singly or in groups of two or three. They were found to be lined with cylindrical epithelium and were similar to those so frequently noted in the hilum of the ovary. Some of the very small cystic spaces, noted macroscopically, were lined with cylindrical ciliated epithelium and had an underlying stroma that stained rather deeply and that consisted of cells with oval vesicular nuclei. This stroma stood out in sharp contrast to the surrounding fibrous tissue. Such cysts frequently contained a little fairly fresh blood. These cysts reminded one very much of the cystic spaces so frequently noted in an adenomyoma, but I believe that they represented only the earlier stages of the larger cysts.

The large cysts were lined with one layer of epithelium which might be cylindrical, cuboidal or almost flat. *Projecting into some of the cysts were papillary folds.* These occasionally occurred as delicate, irregular, finger-like projections, but in the main as blunt, single or branching outgrowths. All of them were covered over with one layer of epithelium. The stroma of the papillary masses had in many places undergone almost complete hyaline degeneration, and in a few liquefaction of this hyaline material had taken place. Even in some of the larger cysts a moderate amount of fresh blood was present. The stroma cells beneath the cyst epithelium had in some places become swollen and spherical and were filled with yellow or brown pigment indicating the absorption of blood at some previous time.

---

* From the Gynecological Department of the Johns Hopkins Hospital.

On the surface of the tumor were a moderate number of vascular adhesions, and on the under and protected side of these the peritoneal cells had become cuboidal as is common on the under side of tubal or ovarian adhesions.

From the above description it will be seen that the dense matrix of the tumor consisted essentially of fibrous tissue and that scattered throughout this were multiple cysts, in large measure similar in character, some of which had small papillary masses projecting into them. Had the tumor developed in the abdominal cavity, I believe that in all probability it would have been a multilocular cystoma, but as it lay between the abdominal muscles and skin a rapid cystic growth was much more difficult, and the fibrous tissue was thus allowed to keep pace with the cystic formation.

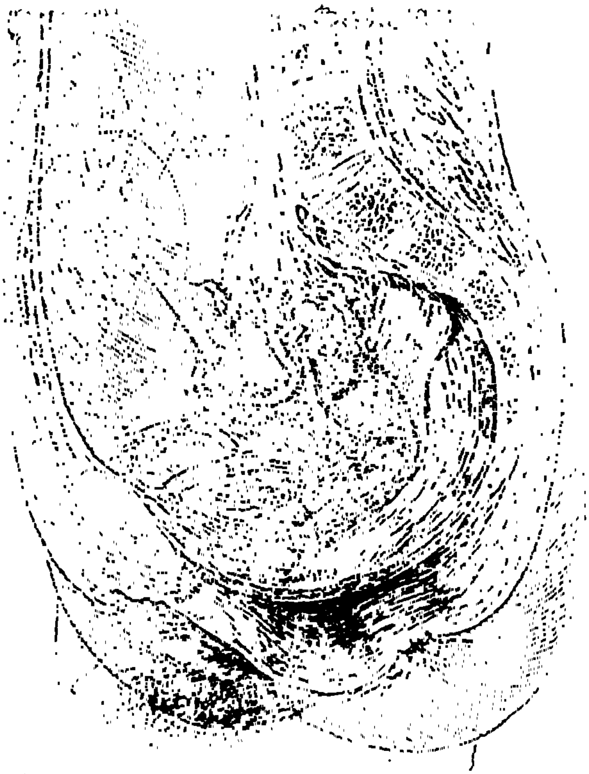

Fig. 1.—OVARIAN PEDICLE PASSING FROM UTERUS, OUT THROUGH A HERNIAL RING IN THE ABDOMINAL WALL. A schematic representation of the pelvic structures as found at operation. The uterus and left appendages were normal. The right tube was unaltered, but passing from the uterus where the right ovary should have been was a band 1 cm. broad. This ran upward and outward and passed out through an abdominal ring to the outer side of the right rectus. At the ring a finger could be passed completely around this pedicle. It was nowhere adherent to the ring. A glance at the umbilicus will indicate the exact location of the ring. On looking through the ring a small portion of the glistening tumor could be readily seen. The dotted line indicates the relative size of the tumor.

There was no sign of malignancy.

THE PRESENCE OF OVARIES IN HERNIAL SACS

The occurrence of ovaries and ovarian tumors in hernial sacs is of particular interest in this connection. I shall, therefore, briefly discuss the more important contributions made in this field.

The ovary has a rather free excursus, and it is not to be wondered at that where an inguinal or femoral hernia exists the ovary and often the tube form part of the contents of the hernial sac. Puech[1] in 1879 contributed a most interesting article on hernia of the ovary. In addition to his own cases, he refers to those of Pott, Lassus, Deneux, Guersant, Parker, Bruny, Warren, Méadows, Cusco, Coote, Englisch, Weinlechner, MacCluer, Sonnenburg, Werth and Rheinstaedter. In brief his paper says that the ovary may pass out at any of the natural abdominal openings, and that, when it does so, it is most frequently by way of the femoral or inguinal ring. The inguinal hernia, which is the more frequent, may be congenital or accidental. The congenital hernia is produced by a condition analogous to the descent of the testicle. In eighty-eight cases of hernia containing the ovary, fifty-four were incontestably congenital, seventeen doubtful and seventeen accidental. The congenital hernias were unilateral in twenty-seven cases, bilateral in twenty-seven cases. In the unilateral cases the left side was more frequently involved. In cases of double hernia the presence of the ovaries in the hernial sac was sometimes associated with defective development of the generative organs. Puech had records of sixteen cases in which the ovary was contained in a femoral hernia. In eleven of these cases the hernia was on the right side and in four on the left.

The uterus or one of its cornua was found ten times in the sac in cases of inguinal hernias, three times among the femoral hernias.

Dr. Joseph C. Bloodgood tells me that he has had two cases of femoral hernia with the ovary lying in the hernial sac.

Several years ago I operated on a child in Cambridge for an inguinal hernia. The sac contained the right tube and ovary. They were so intimately blended with the sac that it was impossible to save them, and they were removed preparatory to doing a radical operation.[2]

My experience with ovaries in hernial rings associated with lack of development of the generative organs has been limited to one case.[3]

A postoperative hernia occasionally contains an ovary. I reported a case of this character several years ago.[4] The patient had had an appendix abscess, which it had been necessary to drain liberally. The resultant hernia in the scar was very tender and in dissecting it out I found that the sensitiveness was due to the presence of the right ovary contained in and adherent to the hernial sac.

OVARIAN TUMORS DEVELOPING IN THE INGUINAL CANAL

Since one or both ovaries may occasionally be found in the inguinal canal, we should not be surprised to find now and then a case in which such an ovary undergoes tumor development. Rheinstaedter[5] in 1878 reported the case of a woman, 68 years of age, who had an elongate oval tumor in the neighborhood of the clitoris. In addition, there was a right-sided globular mass, which was found to be a right inguinal hernia. The oval tumor was larger than a child's head, elastic and apparently fluctuant. The overlying skin was normal. A probable diagnosis of ovarian tumor in a left inguinal hernia was made. Six months later the left hernial sac was opened. The tumor was easily raised and its broad pedicle apparently containing the tube and round ligament was tied off, some adherent loops of small bowel were loosened and pushed up into the abdomen, and the wound closed. The tumor weighed 750 gm. Careful examination of the right hernia revealed the presence of the ovary in the sac.

[2] This case was reported and illustrated in an article published by Dr. Frank T. Andrews (Hernia of the Ovary and Tube, THE JOURNAL A. M. A., Nov. 24, 1906, p. 1707). Dr. Andrews' article gives an excellent résumé of hernia of the ovary and tube, and likewise contains a long tabulation of cases heretofore observed.

[5] [illegible] Angiosarkoma Ovarii in einem [illegible] 1878, ii, 545.

Marchand, who made the microscopic examination, diagnosed the tumor as an angiosarcoma.

Rheinstaedter, in reviewing the literature on the subject, was able to find only one case in which an ovarian tumor in an inguinal hernia reached the size of a child's head. This was the case observed by Cazati and quoted by Beigel. The hernial sac contained a portion of an ovarian cyst, the remainder of which lay in the pelvis.

Of solid ovarian tumors contained in hernias he mentions only a case of Guersant reported by Englisch.

Fargas,[6] in 1890, described the case of a woman, aged 38, who had a tumor the size of a man's head occupying the right inguinal and labial region. On the left side was an inguinal hernia containing an ovary, which was easily reducible. The patient said that until eight years previous the right side had presented the same appearance as the left, and Fargas, therefore, diagnosed the tumor as a right-sided ovarian cyst. Six years prior to *observation the right hernia had become irreducible*, and after that had gradually increased in size.

The hernial sac was opened and the cyst lay free from adhesions. Its pedicle was tied off as in an ordinary ovariotomy and the tumor removed. The patient made a good recovery. The cyst was reticulated (multilocular). Fargas confessed that it might have been confounded with a cyst of the round ligament, but its topography *rendered its source certain. The woman had had* normal menstruation and had borne two children during the existence of this tumor.

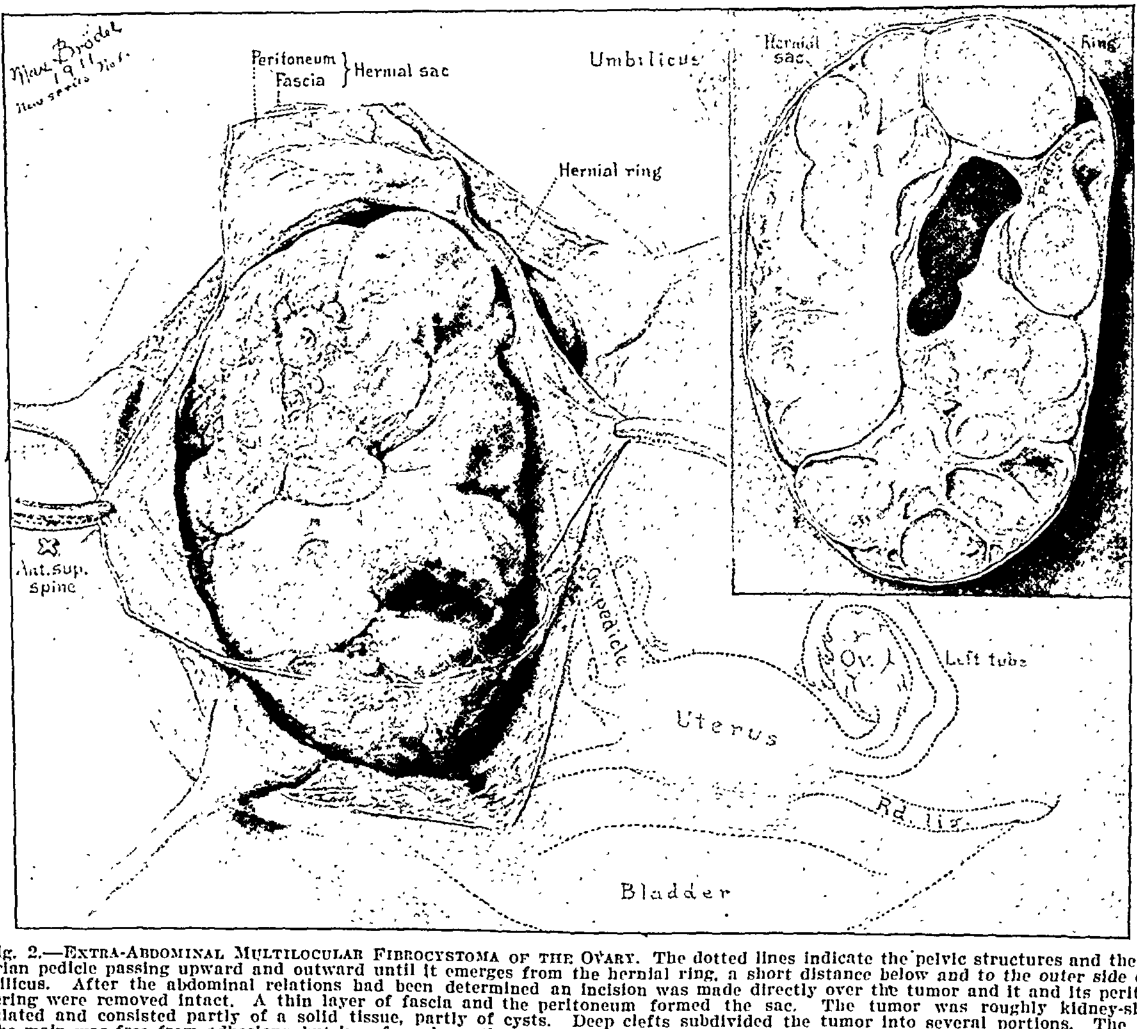

Fig. 2.—EXTRA-ABDOMINAL MULTILOCULAR FIBROCYSTOMA OF THE OVARY. The dotted lines indicate the pelvic structures and the right ovarian pedicle passing upward and outward until it emerges from the hernial ring, a short distance below and to the outer side of the umbilicus. After the abdominal relations had been determined an incision was made directly over the tumor and it and its peritoneal covering were removed intact. A thin layer of fascia and the peritoneum formed the sac. The tumor was roughly kidney-shaped, lobulated and consisted partly of a solid tissue, partly of cysts. Deep clefts subdivided the tumor into several portions. The tumor in the main was free from adhesions, but in a few places there were points of union between the tumor and the peritoneal covering. The drawing in the *right upper corner shows the tumor* on section. The fibrous tissue is abundant, but at this level the cysts predominate. The clefts are seen to have extended through the tumor. It was possible to lift the various segments out without disturbing the remaining ones. Figure 3 gives the real form of the tumor when liberated from pressure.

Seymour[7] in 1897 reported the case of a woman aged 48. Two years before coming under observation a small *tumor had appeared in the right groin.* It was somewhat sensitive, hard and irreducible. An inguinal hernia with possibly an incarcerated omentum without strangulation was thought of. At operation the tumor was found attached to the uterus by a pedicle, 4 inches long and ¾ inch in diameter. This passed out through the inguinal ring to the under surface of the upper end of the tumor in the inguinal canal. The pedicle was tied off and the sac closed. The tumor was ovoid in shape, 4 inches in length and 8 inches in circumference. The microscopic report was spindle-celled sarcoma.[8]

AN OVARIAN CYST PROTRUDING INTO THE INGUINAL CANAL

Baldy[9] in 1898 reported an interesting case of this character. Two years before coming under Baldy's observation the patient had noticed a small pedunculated tumor in the right inguinal region. This had continued to grow until it was as large as an egg and had then been removed. A year later a larger and similar growth had been present and had also been removed. When Baldy saw the patient the growth was as large as a fist. A pelvic examination revealed a mass filling the right side of the pelvis.

At operation, an incision was made directly over the growth and the tumor freed down to a thick, broad, short pedicle which passed into and through the inguinal canal. The attachments of the pedicle in the canal were freed and the finger forced into the abdomen when it was found that the tumor was a continuation of a large intra-abdominal mass.

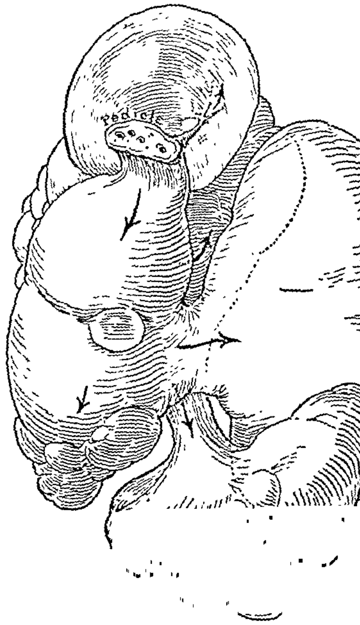

Fig. 3.—An Extra-Abdominal Multilocular Fibrocystoma. A schematic representation of the manner in which the tumor tended to develop when relieved from its surrounding pressure. It in reality consisted of four lobes similar in character and joined together by broad or narrow pedicles.

When the abdomen was opened in the median line, the pedicle of the inguinal growth was found springing from a large intraligamentary tumor similar in character. The left uterine appendages were normal. A supravaginal hysterectomy was performed and the hernial ring closed. The patient made an uninterrupted recovery.

AN OVARIAN CYST LYING PARTIALLY IN A FEMORAL HERNIA

This condition is exceptionally rare. Dellhaes[10] in 1885 cited the case of a woman, aged 55, who entered the hospital in 1879 on account of ascites. For four years she had complained of discomfort in the lower abdomen, and there had been an increase in size in the right side. Thereafter she had had a crural hernia on the right side and for the last nine months a similar hernia on the left. The right was reducible, the left irreducible.

After the patient had been built up to some extent and after the ascitic fluid had been removed several times by puncture, a right-sided ovarian tumor, partly solid, partly cystic, was removed.

The left ovary was cystic and enlarged. It was partly situated in the pelvis and had to be separated from a solid cord which passed into the femoral canal. The major portion of the large cystic left ovary lay in the fold of the groin and fourteen days later was removed through a herniotomy incision. This portion was as large as a child's head. The patient made a complete recovery.

A SMALL PORTION OF AN OVARIAN CYST INCARCERATED IN THE ABDOMINAL WALL JUST BELOW THE UMBILICUS

Hopkins[11] in 1894 reported an interesting emergency case. The patient, aged 57, was admitted for a supposed strangulated umbilical hernia. Protruding just below the umbilical opening was an almost black tumor the size of a walnut. Still thinking that it was a strangulated hernia, the operator cut the constricting band and the tumor at once disappeared. The abdominal opening was enlarged and serous and gelatinous material began to pour out. On further exploration a multilocular ovarian cyst, weighing about 25 pounds, was found. This was removed and the patient promptly recovered.

A small portion of this cyst had become strangulated in a small hernial defect just below the umbilicus.

DEFECTS IN THE ABDOMINAL WALL

A study of the weak spots in the abdominal wall is of interest. Levadoux[12] made a most exhaustive examination of the inner appearance of the umbilicus, of the final disposition of the umbilical arteries, the umbilical vein and the urachus, and described in detail how these sometimes blended in such a manner as to form a fibrous sheath that completely covered over the inner umbilical opening. In the course of his studies he also noted weak spots in the fascia just beneath the peritoneum. These openings were usually small and were oval, round or irregular in shape.

On careful scrutiny it has at times been noted that hernias, supposed to be umbilical, were in reality periumbilical and that the umbilicus itself was intact. These defects in the fascia are undoubtedly the cause of such hernias. In July, 1910, I saw, in consultation with Dr. A. H. A. Mayer, a boy, aged 17, who had a small hernial protrusion 4 cm. above and to the left of the umbilicus. This hernial protrusion projected 1 cm. through the fascia and was lobulated, forming a mass 3 cm. in diameter. The patient was of spare build. On cutting down on the hernial sac I found a small defect in the abdominal wall with a small portion of the omentum projecting through it. The omentum was readily returned and the opening easily obliterated with a few sutures.

---

[8] If the fibrous character of a solid ovarian tumor is definite, one is safe in making a diagnosis of fibroma, and if the growth consists of spindle cells and has many mitotic figures and atypical cell changes, one can with justice make a *diagnosis* of sarcoma. There are, however, quite a number of solid tumors of the ovary of the spindle-celled type, in which it is impossible to say from the microscopic examination whether the growth is a sarcoma or a fibroma. In such cases the diagnosis can never be definitely determined unless the patient subsequently develops metastases.

[12] Levadoux, Michel-Joseph: Variétés de l'ombilic et de ses annexes, Thèse Fac. de Méd. et d Pharm. de Toulouse, 1907, No. 711.

Dr. Bloodgood tells me that he observed a case of hernia of the abdominal wall at the semilunar line, that was between the rectus muscle and those forming the lateral abdominal wall. The sac contained non-adherent loops of small bowel. The condition was readily cured. In our case the opening was also at, or near, the semilunar line, and instead of small bowel passing into it the ovary had for some reason occupied the space and later had gone on to tumor development. It is just possible that this weakness in the wall had become particularly accentuated during a pregnancy and that the ovary during its ascent with the pregnant uterus had dropped into the cavity.

In conclusion, I wish to thank Dr. Fred Ray for his kindness in ferreting out the references to the articles read by me in the preparation of this paper, and I am especially indebted to Mr. Max Brödel and the Foundation of Art in Medicine of the Johns Hopkins Medical School for the excellent illustrations.

SOME APPARENTLY OBSCURE CONDITIONS OF THE GASTRO-INTESTINAL TRACT AND THE PRACTICAL APPLICATION OF THE RÖNTGEN RAY IN THEIR DIAGNOSIS *

G. REESE SATTERLEE, M.D.
Attending Physician and Pathologist to the Washington Heights Hospital; Instructor in Medicine in the University and Bellevue Hospital Medical College, New York.
AND
LEON THEODORE LE WALD, M.D.
Director of the Edward N. Gibbs Memorial X-Ray Laboratory; Instructor in Gross Pathology, New York University
NEW YORK

We are not dealing with the obscure conditions of the gastro-intestinal tract as they arise, but mostly with the common pathologic states, often misinterpreted on account of the unsatisfactory methods of diagnosis at the present day. The subject is so broad that we have decided to restrict our paper to the size, position, and motility of the gastro-intestinal tract. Normal patients, or patients with splanchnoptosis with or without intestinal symptoms, constitute our particular theme. Cases of ulcer and malignancy have been omitted on account of limitations of space.

All the cases under consideration have been studied first with regard to the physical signs and the ordinary tests for gastro-intestinal secretions and contents. The Röntgen ray has been used as *an aid and confirmatory* agent in diagnosis. Whereas due consideration in every case has been given to the history, subjective and objective signs, and examination of secretions, we have found progressively downward and they become confirmed the previous diagnosis, it has also shown the error of the previous diagnosis in an astonishing number of cases. A great difficulty in gastro-enterologic work has been the lack of certainty in the results of clinical tests for size, position, and motility of the hollow viscera. The Röntgen ray solves this problem. Every day we meet patients with moderate or severe grades of constipation, not due to obstructions from tumors. They have usually gone the rounds of numerous physicians or dispensaries, and are relieved only by the continuous use of laxatives or cathartics. Their course is nearly always progressively downward and they become confirmed neurasthenics or slaves to the drug habit. Occasionally, without any scientific accuracy on the physician's part, these patients, if they are fortunate, improve by treatment on general principles.

In previous examinations, chemical tests for motility of the stomach and intestine have been unreliable. Peristalsis of the stomach and intestine sometimes can be seen through an abdominal wall that has been thinned out, usually in advanced emaciation. The entire length of time that food takes to pass from the mouth to the anus can be determined by the ingestion of indigestible and non-absorbable foods or chemicals, such as bismuth salts, which can be recognized in the stools. This does not indicate, however, the length of time consumed in digestion by the different portions of the alimentary tract, and is often inaccurate in determining the time of digestion. Tests for determining residual food in the stomach are tedious and very annoying to the patient, and determine only approximately the final result. This, with our other important data, can be shown by the Röntgen ray, in a properly conducted series of plates.

Radiographs of the alimentary tract after the administration of some insoluble substance which obstructs the Röntgen ray, such as the bismuth salts, have been used in Europe since 1904, by Rieder,[1] Holzknecht,[2] C. Kaestle and J. Rosenthal,[3] Franz M. Groedel,[4] A. F. Hertz,[5] and others; and in this country by G. E. Pfahler,[6] Hulst,[7] Pancoast,[8] Cole,[9] and others. The methods will soon be universally applied. Rieder was the first to give large amounts of bismuth salts. He gave from 40 to 50 gm. of bismuth subnitrate in a meal of boiled rice, barley broth, potato puree, spinach, or boiled meat. The bismuth can be administered by mouth or by rectum. Haenisch[10] was the first to give the bismuth per rectum, in the following formula: bismuth subcarbonate 75 gm., bolus alba 300 gm., water 1,000 c.c. We use the bismuth rectal injection and find it a valuable adjuvant to the method by mouth. Kaestle used zirconium oxid instead of bismuth because it was more insoluble. Of the salts of bismuth, the subnitrate was at first extensively used, but it has caused toxic symptoms. Cases of poisoning due to the impurities in the preparation, or to the absorption of the nitrites formed in the intestine, have been reported by E. G. Beck,[11] W. Alexander,[12] L. Lewin,[13] and many others. The subcarbonate of bismuth is apparently non-poisonous and acts in the same way as the subnitrate toward the Röntgen ray. We have had no toxic symptoms in over forty tests in which large quantities were given. Examination of the bismuth stool shows the bismuth passed through chemically unchanged.

Milk, as representing a suitable form of food, is now being used as a menstruum for the bismuth. A serious objection to ordinary milk is the early precipitation of the bismuth, but this can be overcome by the use of the fermented milks which hold the salts in suspension for a much longer time. Our experiments with bismuth suspended in various media demonstrate that the salts mixed with the fermented milk remain in suspension longer than in other fluid foods, as malted milk, sweet milk, buttermilk, and chicken soup. The next best substance is a thick chicken soup. (Fig. 1.)

For the average adult, 75 gm. of bismuth subcarbonate suspended in 500 c.c. of fermented milk is given with the stomach empty. Previous catharsis is unnecessary and inadvisable. The diet for the previous twelve hours must be light and exclusive of meat, fruits, and vegetables. All medication is omitted.

The radiographs have all been taken with the patient in the standing position. The distance from the anode to the plate is 24 inches, with the plate anteriorly and the anode on a level with the umbilicus. The illumination is dorsoventral, with one or two lateral views, as the occasion demands. The duration of the exposure is from one-sixth to four seconds, mostly under one second. It requires an average of from eight to twelve radiographs to examine a patient. Occasionally, a second series is necessary for a control, or a rectal injection to corroborate the colon findings. For experimental purposes, more plates have been taken than are ordinarily necessary for a routine examination. We find that the radiographs after the rectal injection do not give as natural an appearance to the colon as those taken after the administration of the bismuth by mouth. The plates can be taken much sooner, however, as the bismuth mass reaches the cecum within fifteen minutes and is then rapidly expelled per rectum.

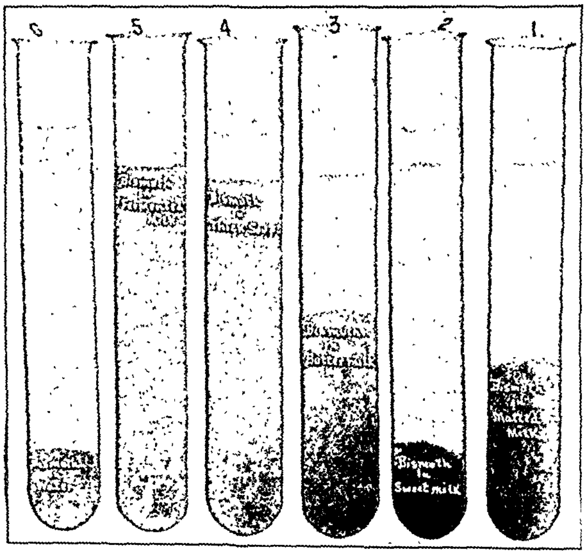

Fig. 1.—Radiograph of substances used for Röntgen-ray test-meals. Each test-tube contains an equal amount of bismuth subcarbonate. It shows the amount of settling fifty hours after suspension. 1. Malted milk and acacia. 2. Sweet milk. 3. Buttermilk. 4. Chicken soup. 5. Fermented milk. 6. Water and acacia. Note the remarkable stability of the suspension of the bismuth in the fermented milk.

We always try to make a primary, a secondary, and a final diagnosis. The primary diagnosis is made from the history, the physical examination, the examination of the gastric contents after a test-meal, and the examination of the feces and the urine. Other examinations are made as the occasion arises. The primary diagnosis is made previous to any consideration of the Röntgen ray.

The secondary diagnosis is made wholly from thorough consideration of multiple Röntgenograms, taken seriatim after the bismuth meal. In every case, the exposures are continued until the last trace of bismuth has left the alimentary tract.

The final diagnosis is made by carefully comparing the primary and secondary diagnoses and weighing the preponderance of evidence offered by the symptomatology.

In estimating the position of the viscera, our technic is to place markers on (1) the tip of the ensiform, on (2) the umbilicus, over (3) the tip of the ninth right costal cartilage, and on (4) the anterior superior spine of the right ilium. The umbilicus, contrary to what we expected, appears to be a fairly well-fixed point, except in very pendulous abdominal walls. It must be remembered, however, though these landmarks are sometimes uncertain, yet if their location is abnormal it is evident on physical examination, and hence allowance can be made.

We shall first mention some of the results, quite constant in nearly all our cases. Our studies on the esophagus have been entirely too superficial as yet to warrant the findings being chronicled. The points in fixation of the stomach agree with those described by anatomists. They are the esophagus and distal end of the first portion of the duodenum, which latter point anatomists say is firmly attached by the duodeno-hepatic ligament (Piersol[14]). In a normal, or at least a non-ptosed well-filled stomach, the shadow of the distal end of the first portion of the duodenum reaches the level of the upper border of the second lumbar vertebræ. The outline of the pylorus is situated opposite the junction of the second and third lumbar vertebræ. For the purpose of classification, we consider that if the lesser curvature is well up above the upper margin of the umbilicus, the stomach is not ptosed. The shape of the stomach varies according to the position of the subject. When the patient is in the standing position, in the greatest number of cases, the shape of the stomach resembles that of a fish-hook, and when in the recumbent ventral position, it simulates a steer's horn. This modifies former anatomic views based on dissections in the dorsal decubitus. When the patient is in the standing position, the long axis is vertical; when he is in the prone position, the long axis in the same subject may be oblique or almost transverse.

In order to determine accurately the size, shape, and position of the stomach, studies of plates made within a few minutes after ingestion of the bismuth meal should be made. During activity of the stomach, peristaltic waves can be seen distinctly as constrictions on the greater and lesser curvatures. These are differentiated from permanent constrictions by the changes in form of the organ in the succeeding plates or by the fluoroscope. The former is, in our estimation, more accurate and practical than the latter. The cardiac end of the stomach empties very quickly and shows the rugæ often plainly marked out by the bismuth. In cases of gastric fermentation, the gas rises in the cardiac end and pushes up the diaphragm, as can be well demonstrated in the radiograph.

The average time required for the normal stomach to empty itself completely of a full bismuth meal is, in our experience, from two and one-half to four hours. It is difficult to prove atony of the gastric musculature, but stasis and permanent pouches can be demonstrated, some of the bismuth remaining in the lower pole as long as ten hours after ingestion.

---

[14] Piersol, George A.: Human Anatomy, 1909 ed.

The motility of the stomach in nearly all cases appears to be most rapid during the early part of digestion. Some stomachs seem to rest after the first thirty minutes to an hour. After that, they still contain about one-quarter of the amount of the original contents, which is discharged in a variable time. The end motility of the stomach is apparently not influenced by the amount of free hydrochloric acid in the gastric contents. The early activity in certain cases of hyperchlorhydria is increased, however. This is demonstrated by the serial radiographs taken up to the final emptying of the organ. The dilated stomachs almost invariably show a slow motility, especially in completion of the act.

The study of the small intestine has so far been unsatisfactory, especially so of the duodenum, on account of the rapidity with which the bismuth meal passes through this part. The first portion of the duodenum can usually be identified by a small mass of bismuth, the so-called "bishop's cap," separated from the pyloric antrum by the outline of the pyloric muscle. The pyloric ring, as thus seen, averages 3/16 of an inch in width. In most of our cases, splashes of bismuth appeared in the jejunum within a few minutes after the entrance of the meal into the stomach, and it is the exception to find the small intestine free from bismuth within ten minutes after taking the food.

The course of the bismuth in the jejunum is first to the left iliac region, but it quickly settles in the median line. It appears between the umbilicus and the brim of the true pelvis in non-ptosed conditions and enters quickly the true pelvis in ptosed states.

We find the progress of the bismuth in the small intestine to be comparatively rapid. In the twenty-seven cases studied for this paper, the earliest time within which the bismuth has reached the cecum was one hour. This occurred in two adults, and in three children about twelve years of age, one of whom had a pan-visceroptosis. Rieder[1] and Goldthwaite[15] consider two hours to be the most rapid time in which the bismuth can reach the cecum, while Groedel and Hertz say that they have not seen the bismuth reach the cecum in two hours, and that four hours is the shortest time it takes. In our slowest cases, so far, the bismuth has taken five hours to reach the cecum. The average time seems to be two hours. Complete emptying of the small intestine can be determined in only nine out of the twenty-seven cases. In these cases it averages about six hours, and varies from four to seven hours. The estimation of the time is rendered uncertain by a dilated, sacculated, or "residual" stomach, which constantly sends over splashes of bismuth into the small intestine until the organ has completely emptied itself.

Normally, the cecum is always situated well above the brim of the true pelvis. When the colon is ptosed, the cecum lies near the brim and in severe cases often hangs over into the true pelvic cavity. Dilatation of the colon appeared in eight cases, in which the colon had not been emptied in forty-eight hours.

In three of our cases, the vermiform appendix can be plainly seen, the lumen being patent and filled with bismuth. This occurred in one case after a cecum had become much engorged, and in another before the cecum had been filled. In these three cases, the situation and size could be proved. In one of the patients the bismuth remained in the appendix four days after the cecum had been emptied.

In one of our patients, with a complete transposition of all the viscera and a coloptosis, a subacute appendicitis seemed probable. The radiograph demonstrated the cecum well below the line leading from the anterior superior spine to the umbilicus and on the left side. McBurney's point, where the place of tenderness existed, corresponded to the hepatic flexure. An operation has not been performed, as the pain and tenderness were probably caused by a localized colitis, as evidenced by the mucus in the stools. The bismuth radiogram proved the locality of the cecum, and, if it did not absolutely disprove the diagnosis of appendicitis, at least showed that the patient's appendix was on the left side and well down in the pelvic cavity. The patient improved under treatment, which was general, and local for the colitis, with an abdominal belt for support for the coloptosis.

Our results as to the position, size, shape, and motility of the colon have been very satisfactory. The organ can be readily identified by its size, position, and sacculations. We have classified the cases into (1) normal colons, (2) abnormally long and looped colons, (3) ptosed colons, with or without abnormal length and loops, and (4) abnormally short colons. As to the shape of the colons, the following terms have suggested themselves to our minds: (a) straight, transverse colons, the strictly normal; (b) the U-shaped colon, caused by one large loop, dipping down toward the pelvis; (c) the V-shaped colon, which is similar; (d) the double U-shaped colon, with one loop from the hepatic and another from the splenic portion of the transverse colon; (e) the W-shaped colon, similar to the last; (f) the diamond-shaped colon, with the transverse portion running abruptly upward from the hepatic to the splenic flexure; and (g) the dragon-shaped colon. Our control radiographs show the constancy in the shape and posi-

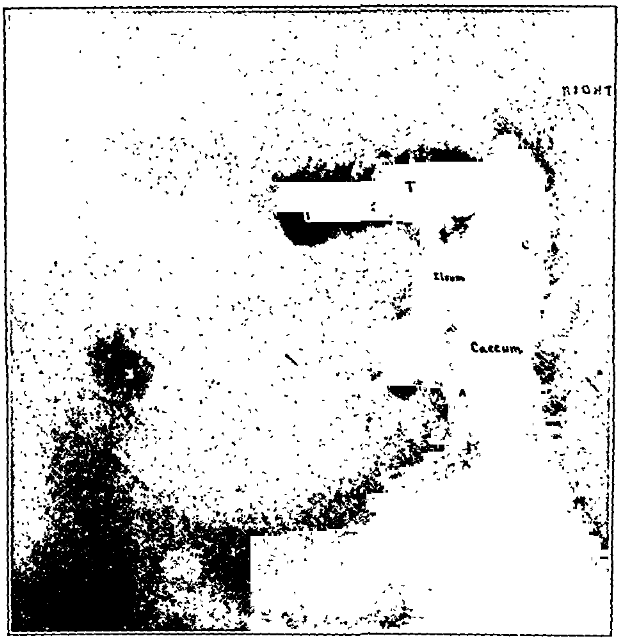

Fig. 2.—Radiograph taken five hours after the ingestion of a bismuth meal (Case 1). A, base; V, the tip of the vermiform appendix; U, umbilicus; T, transverse colon; H, hepatic flexure; B, remnants of bismuth in coils of small intestine; S. S., anterior superior spines.

tion of these colons, and in our estimation prove them to be peculiar to the individual. In some cases, hidden folds in the colon occur which give in later radiographs, after the colon is well filled, a much longer and looped appearance.

A ptosis of the colon is recognized by the low position of the caput coli and of the hepatic flexure. The hepatic flexure is normally at or above the level of the umbilicus. The loops of the colon may exist without a coexisting ptosis, as shown in some of our cases. The most constant point of fixation of the colon is at the splenic flexure where the intestine is attached by the phrenocolic ligament to the left abdominal wall under the spleen (Piersol). The average height of the splenic flexure, in our cases, is 4 inches above the umbilicus, a point which varies but little except in some extreme cases of coloptosis.

Motility of the colon varies, often out of proportion to its length. The motility in ptosed colons we think is always slow.
